A.2.4. Diel Trends

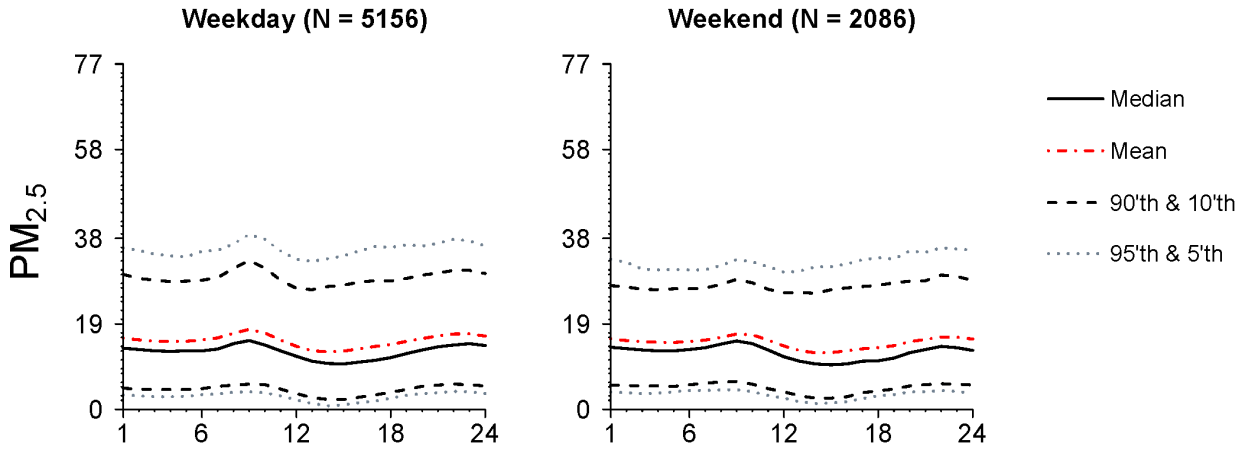

Figure A-157. Diel plots generated from all available hourly FRM-like $PM_{2.5}$ data, stratified by weekday (left) and weekend (right), in Atlanta, GA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

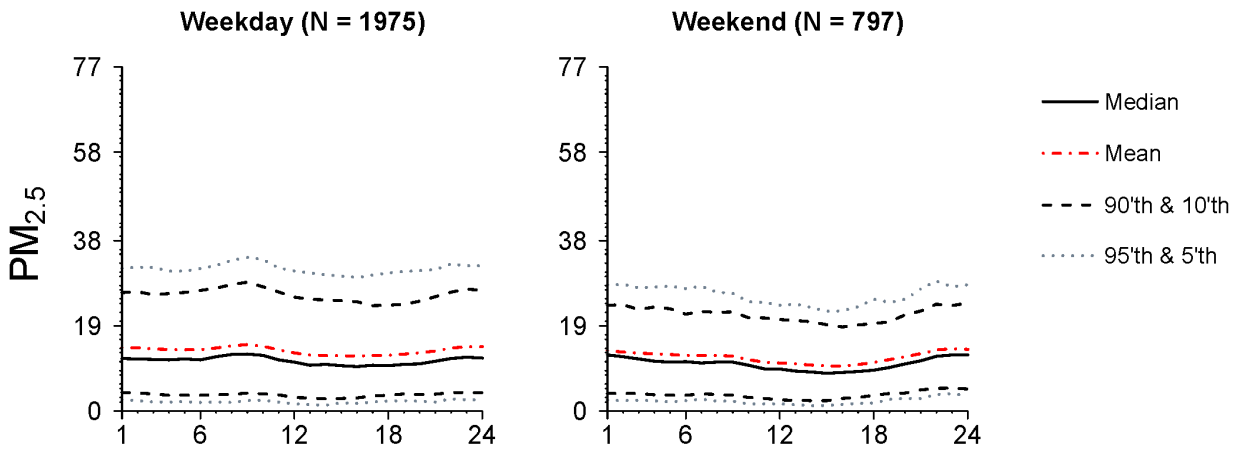

Figure A-158. Diel plots generated from all available hourly FRM-like $PM_{2.5}$ data, stratified by weekday (left) and weekend (right), in Chicago, IL. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

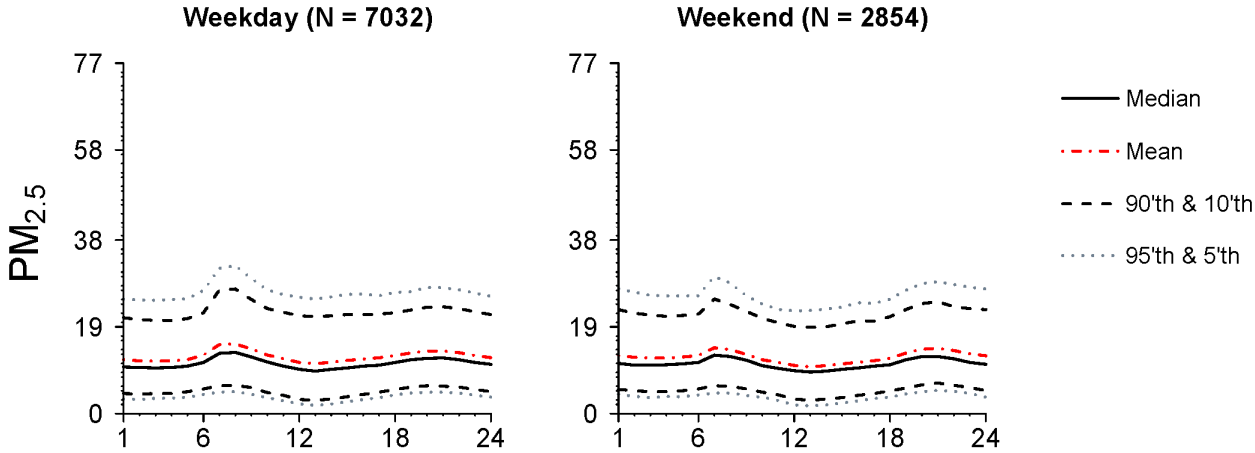

Figure A-159. Diel plots generated from all available hourly FRM-like $PM_{2.5}$ data, stratified by weekday (left) and weekend (right), in Houston, TX. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

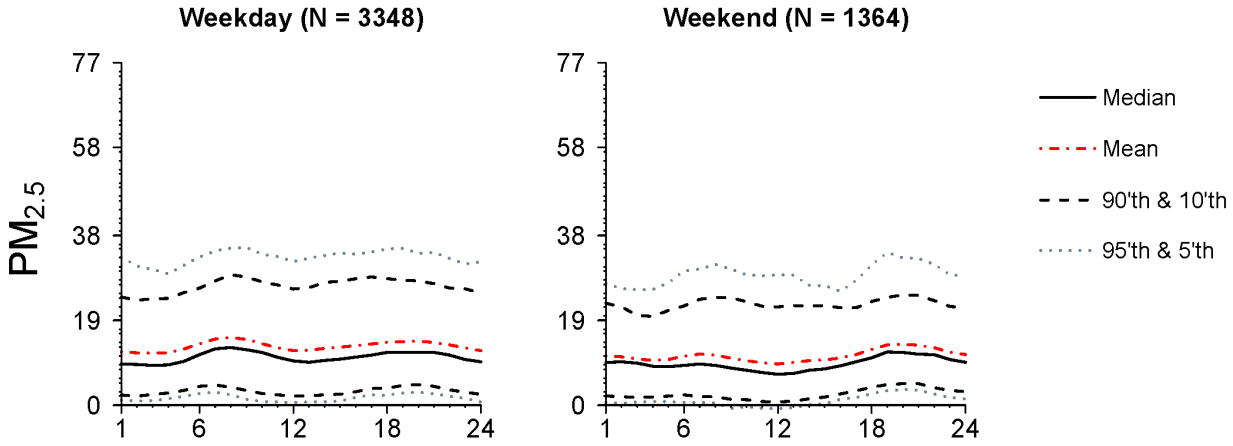

Figure A-160. Diel plots generated from all available hourly FRM-like $PM_{2.5}$ data, stratified by weekday (left) and weekend (right), in New York, NY. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

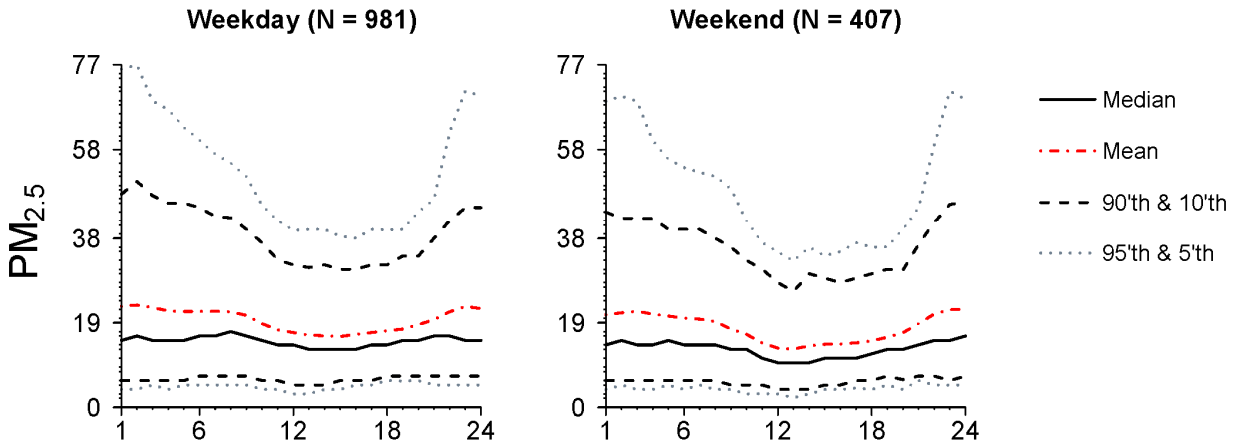

Figure A-161. Diel plots generated from all available hourly FRM-like $PM_{2.5}$ data, stratified by weekday (left) and weekend (right), in Pittsburgh, PA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

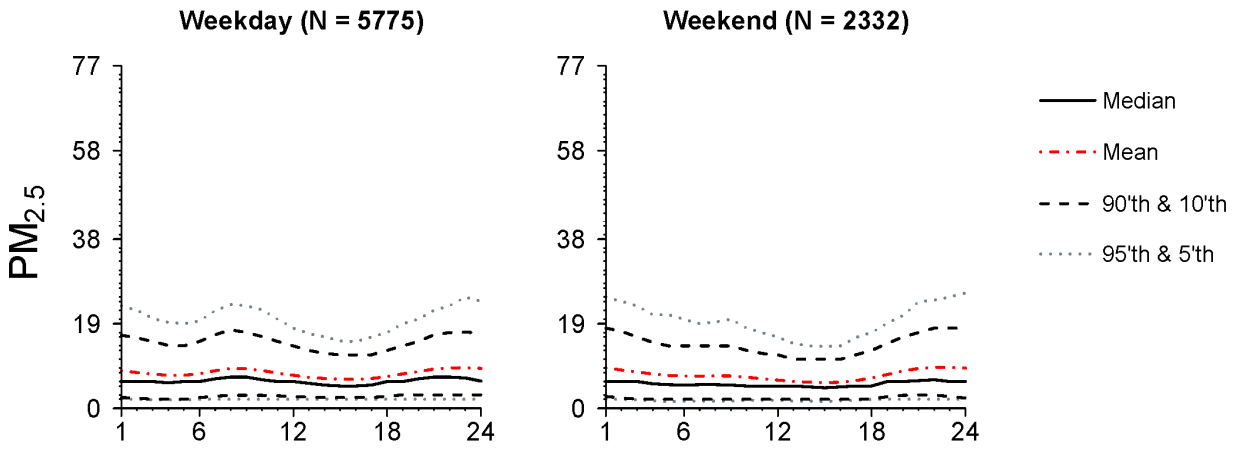

Figure A-162. Diel plots generated from all available hourly FRM-like $PM_{2.5}$ data, stratified by weekday (left) and weekend (right), in Seattle, WA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

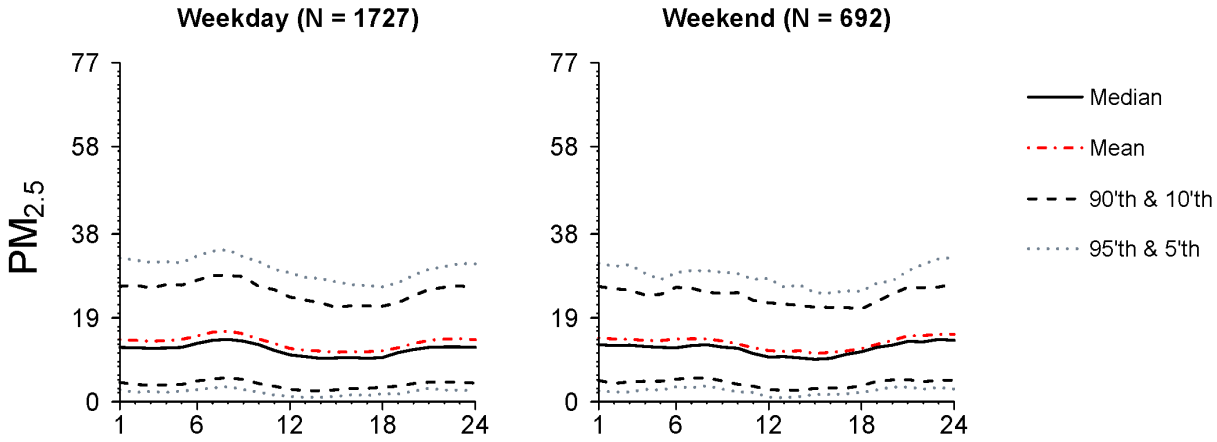

Figure A-163. Diel plots generated from all available hourly FRM-like $PM_{2.5}$ data, stratified by weekday (left) and weekend (right), in St. Louis, MO. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

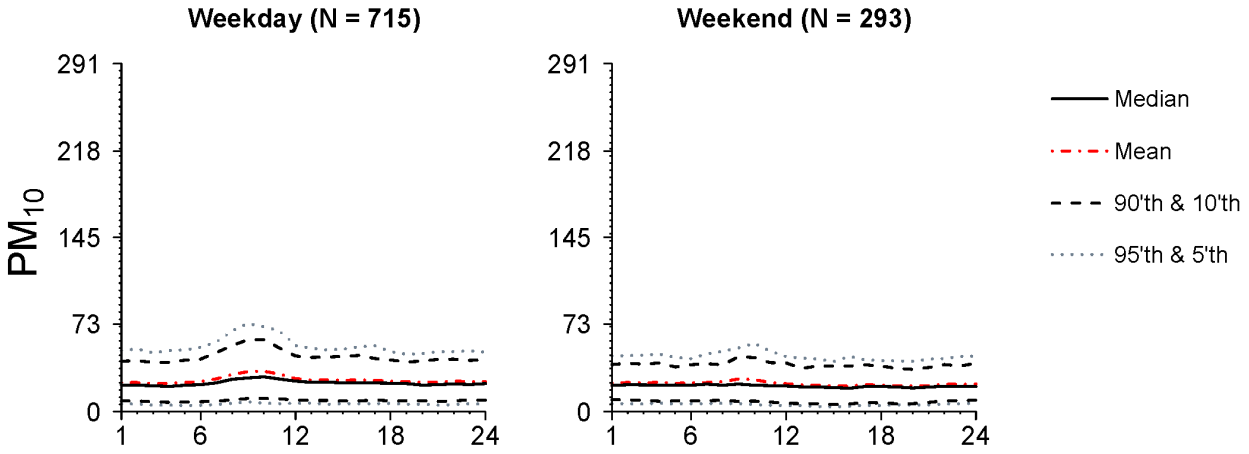

Figure A-164. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Atlanta, GA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

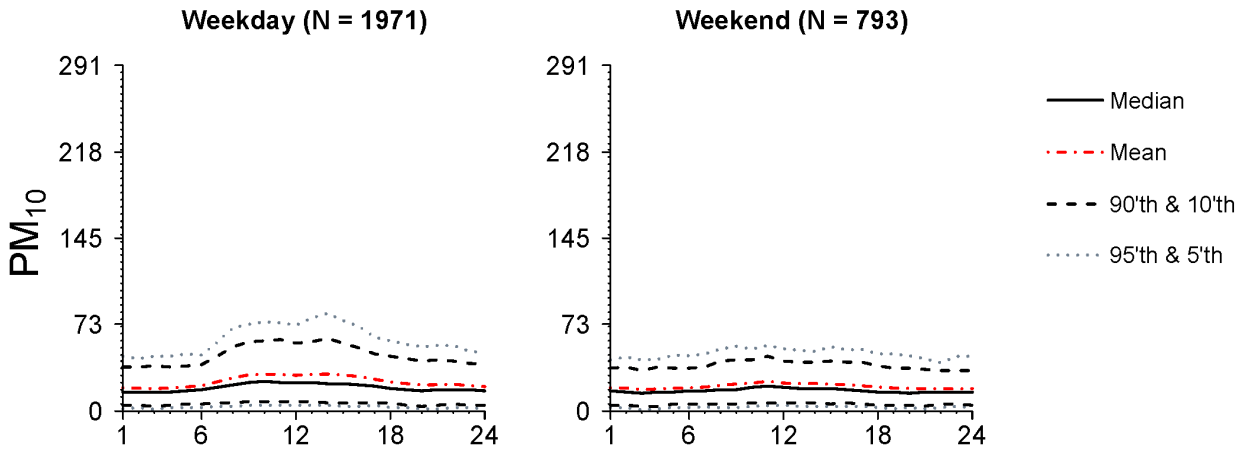

Figure A-165. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Chicago, IL. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

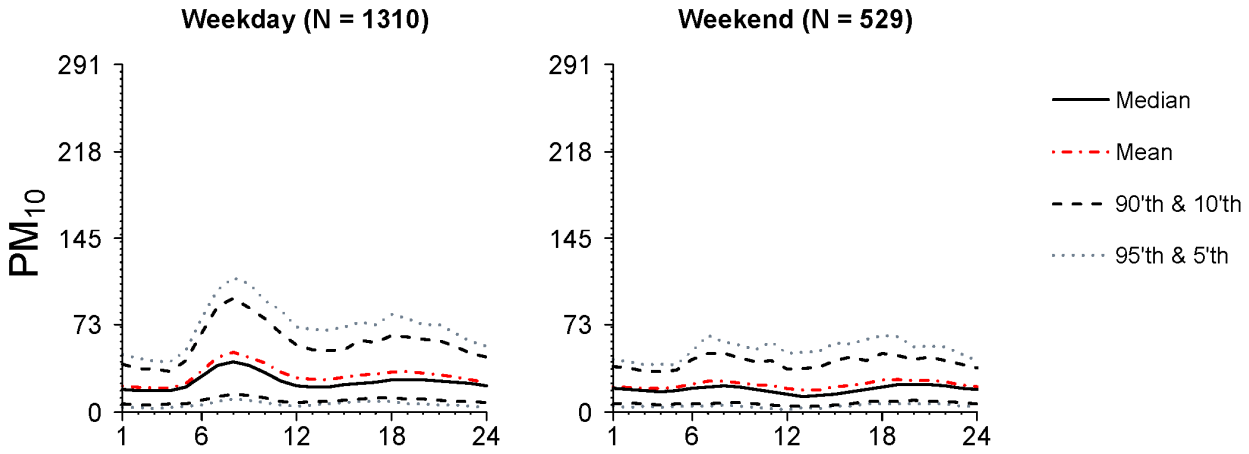

Figure A-166. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Denver, CO. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

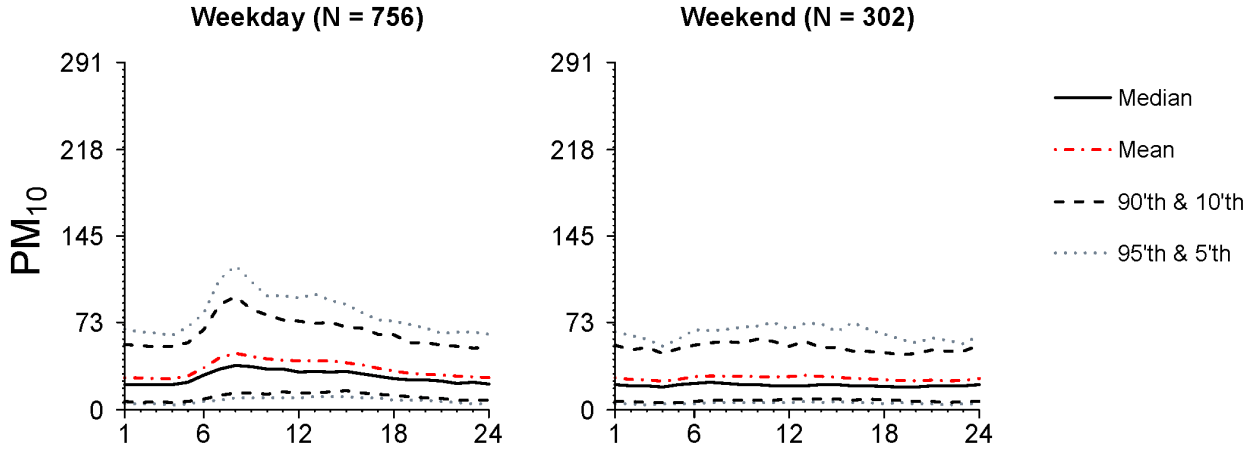

Figure A-167. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Detroit, MI. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

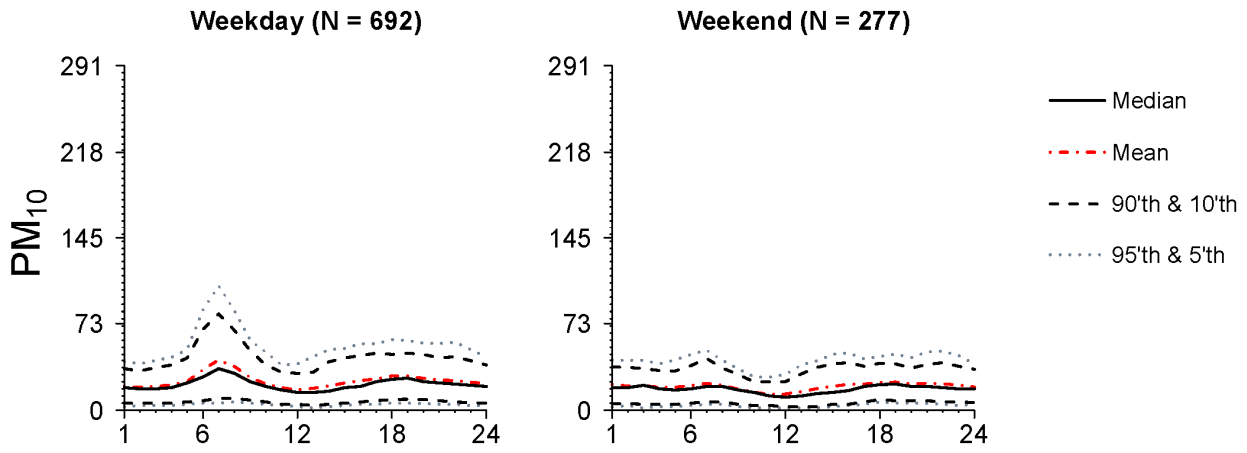

Figure A-168. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Los Angeles, CA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

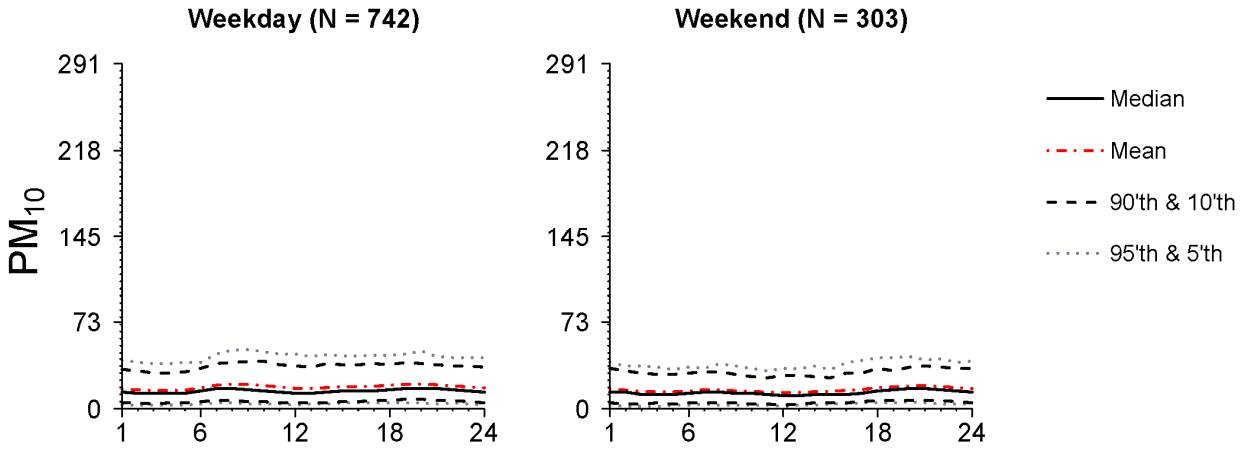

Figure A-169. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Philadelphia, PA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

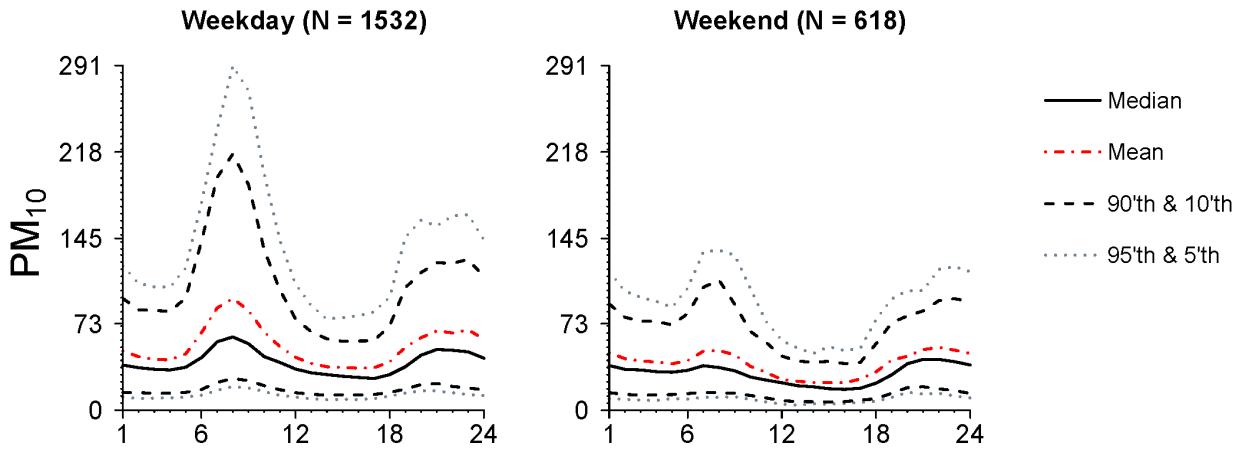

Figure A-170. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Phoenix, AZ. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

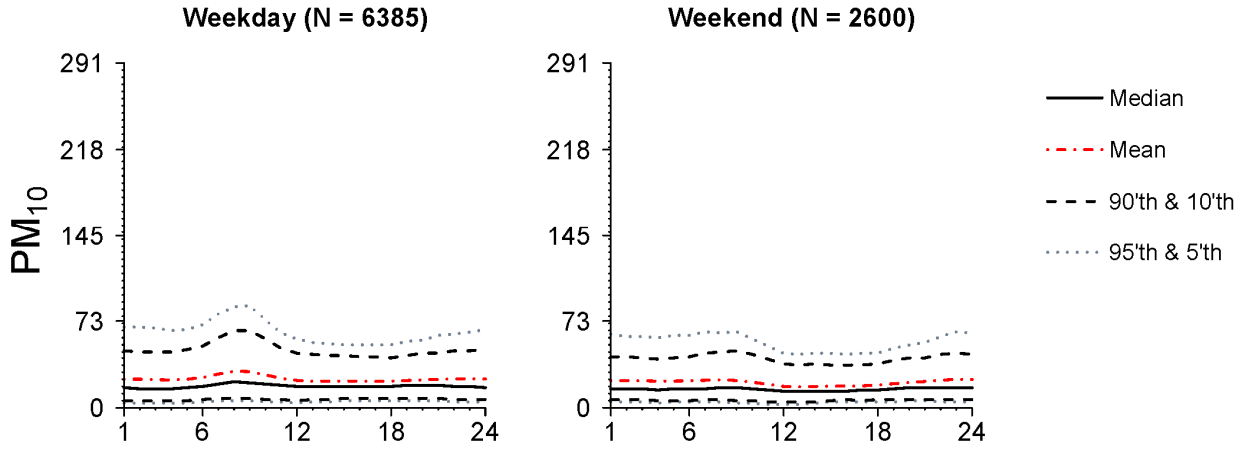

Figure A-171. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Pittsburgh, PA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

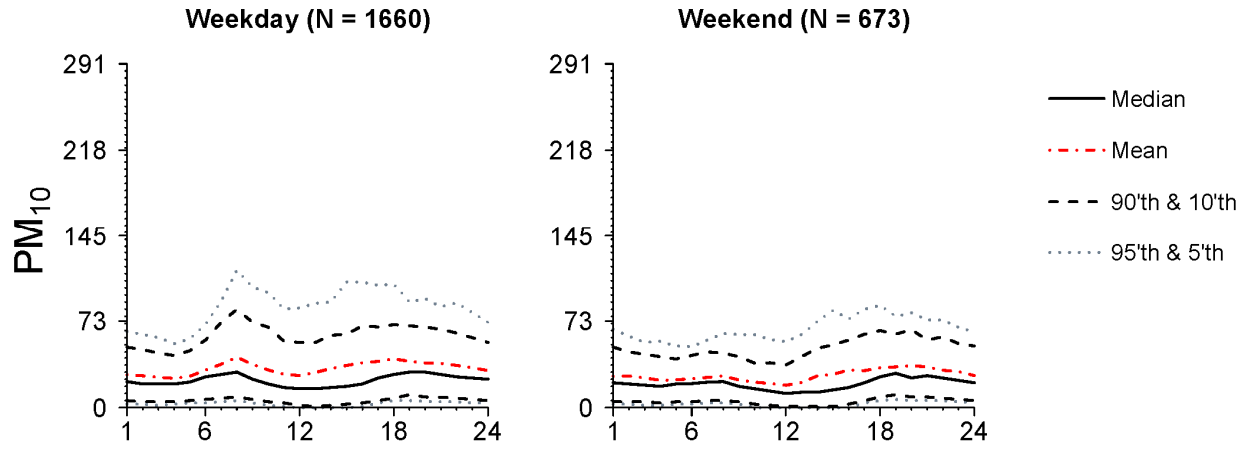

Figure A-172. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Riverside, CA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

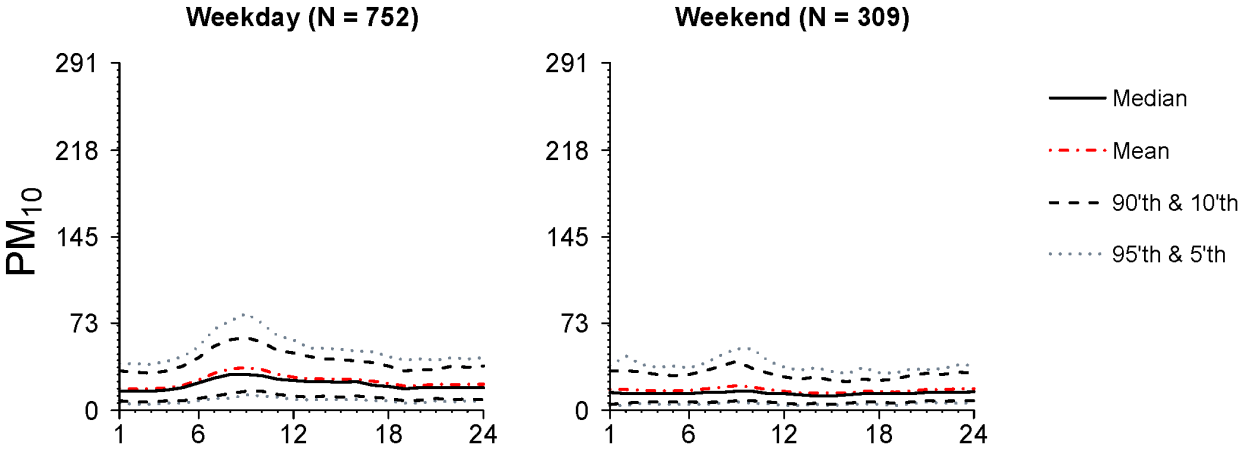

Figure A-173. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in Seattle, WA. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

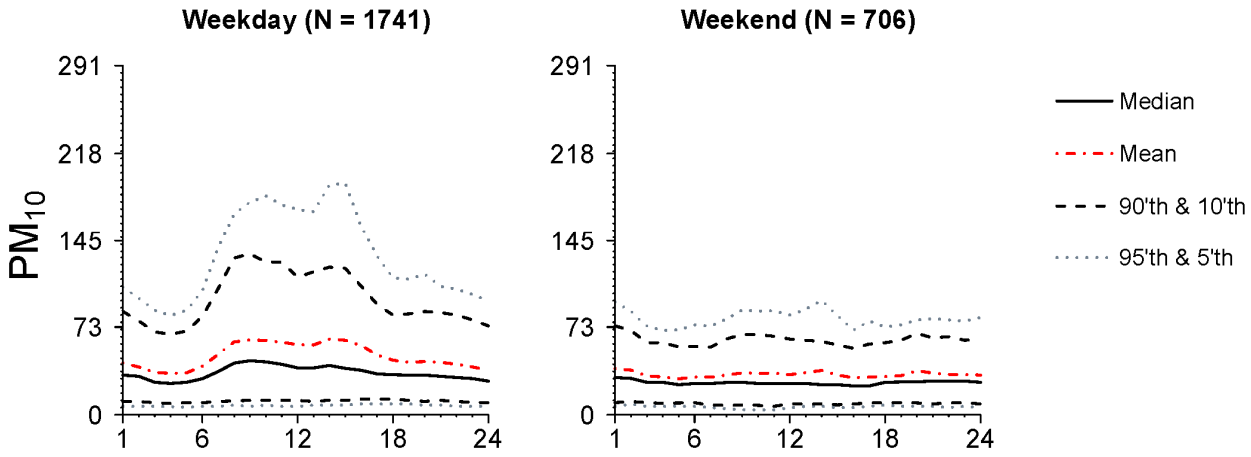

Figure A-174. Diel plot generated from all available hourly FRM/FEM PM_{10} data, stratified by weekday (left) and weekend (right), in St. Louis, MO. Included are the number of monitor days (N) and the median, mean, 5th, 10th, 90th and 95th percentiles for each hour.

A.2.5. Copollutant Measurements

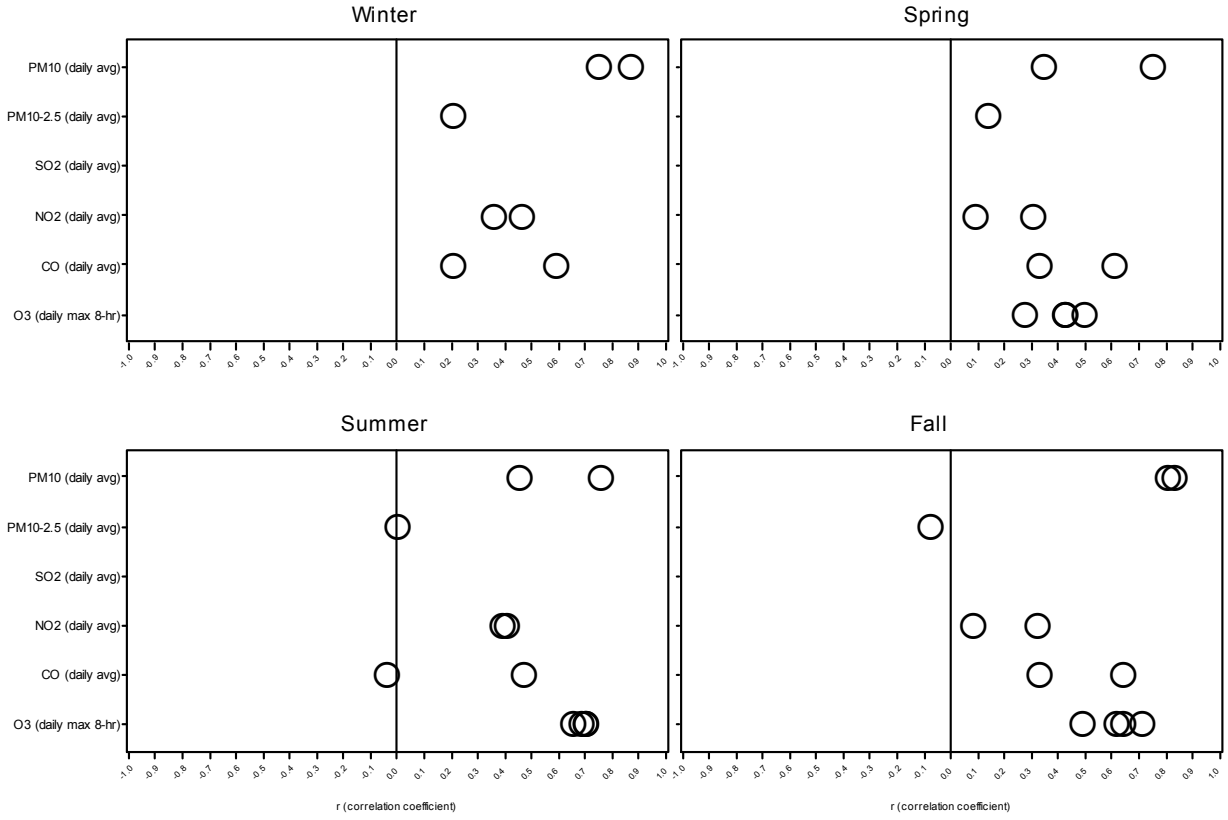

Figure A-175. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Atlanta, GA, stratified by season (2005-2007). One point is included for each available monitor pair.

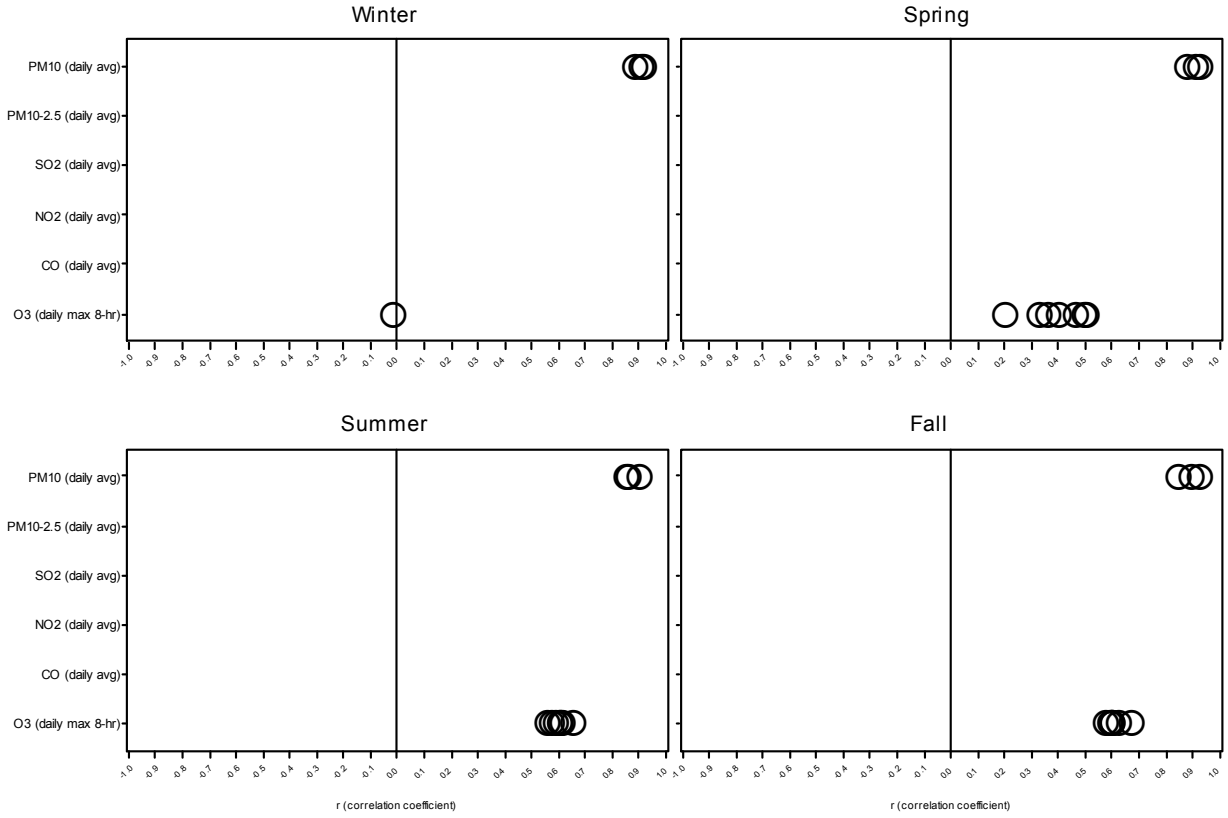

Figure A-176. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Birmingham, AL, stratified by season (2005-2007). One point is included for each available monitor pair.

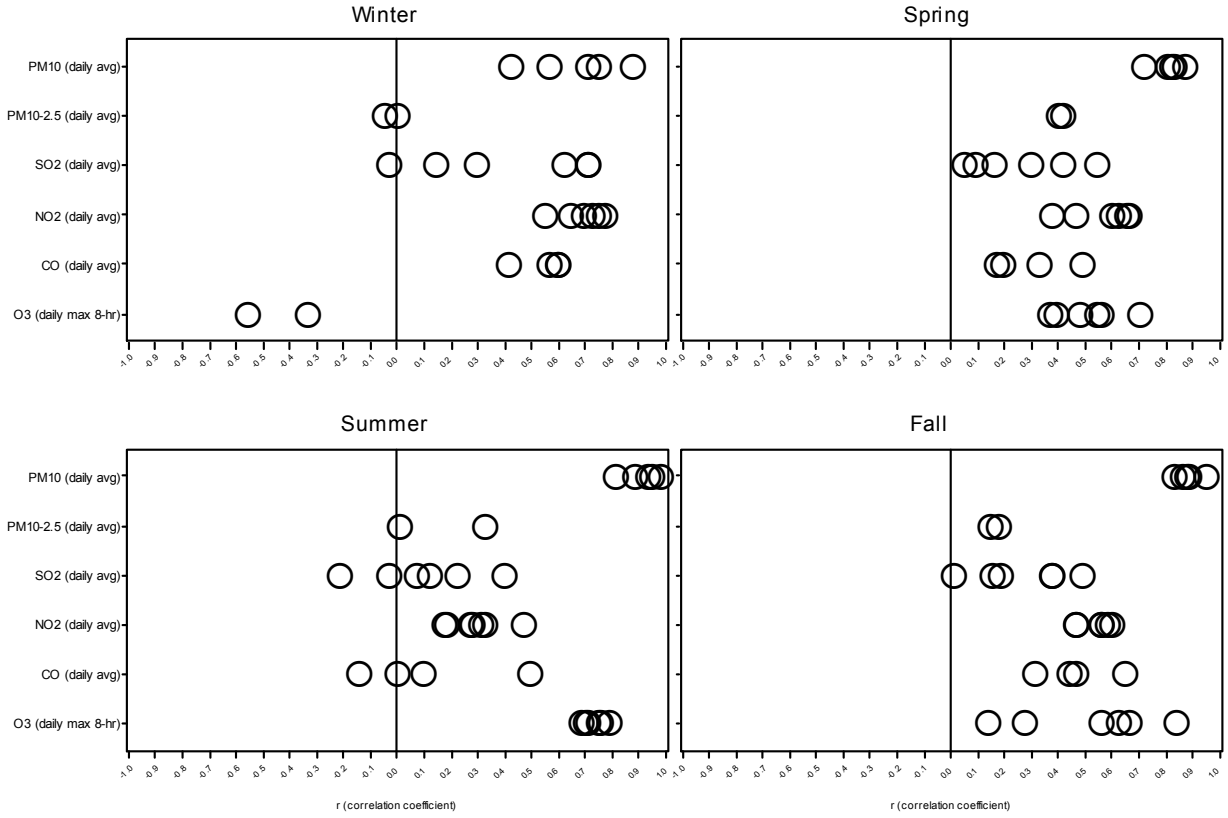

Figure A-177. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Boston, MA, stratified by season (2005-2007). One point is included for each available monitor pair.

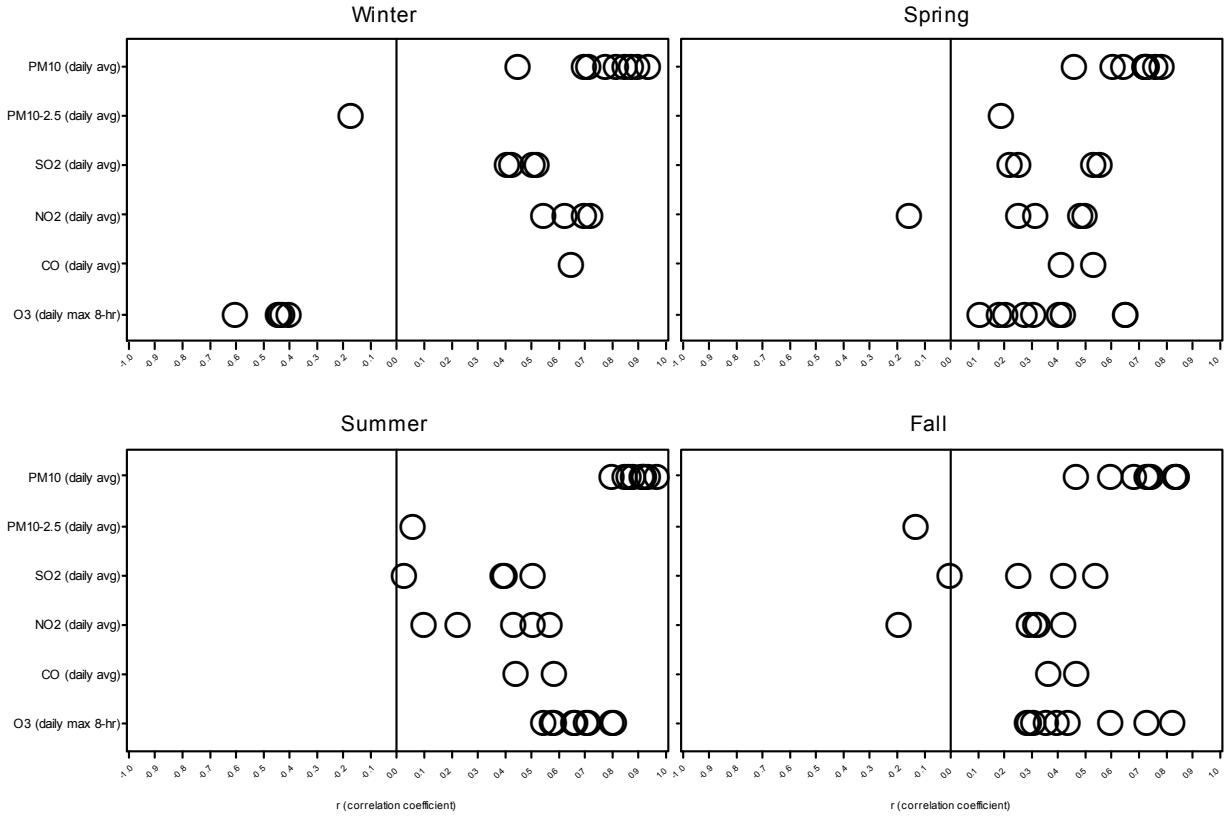

Figure A-178. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Chicago, IL, stratified by season (2005-2007). One point is included for each available monitor pair.

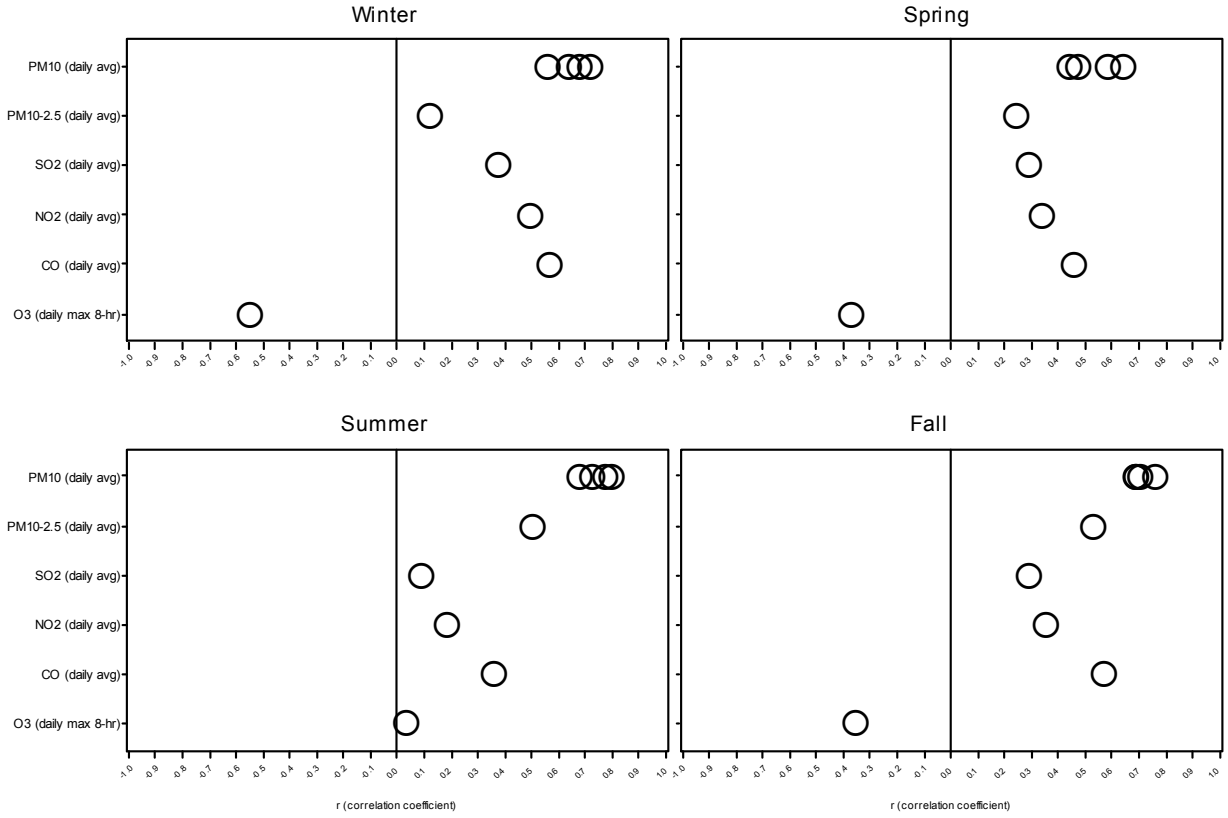

Figure A-179. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Denver, CO, stratified by season (2005-2007). One point is included for each available monitor pair.

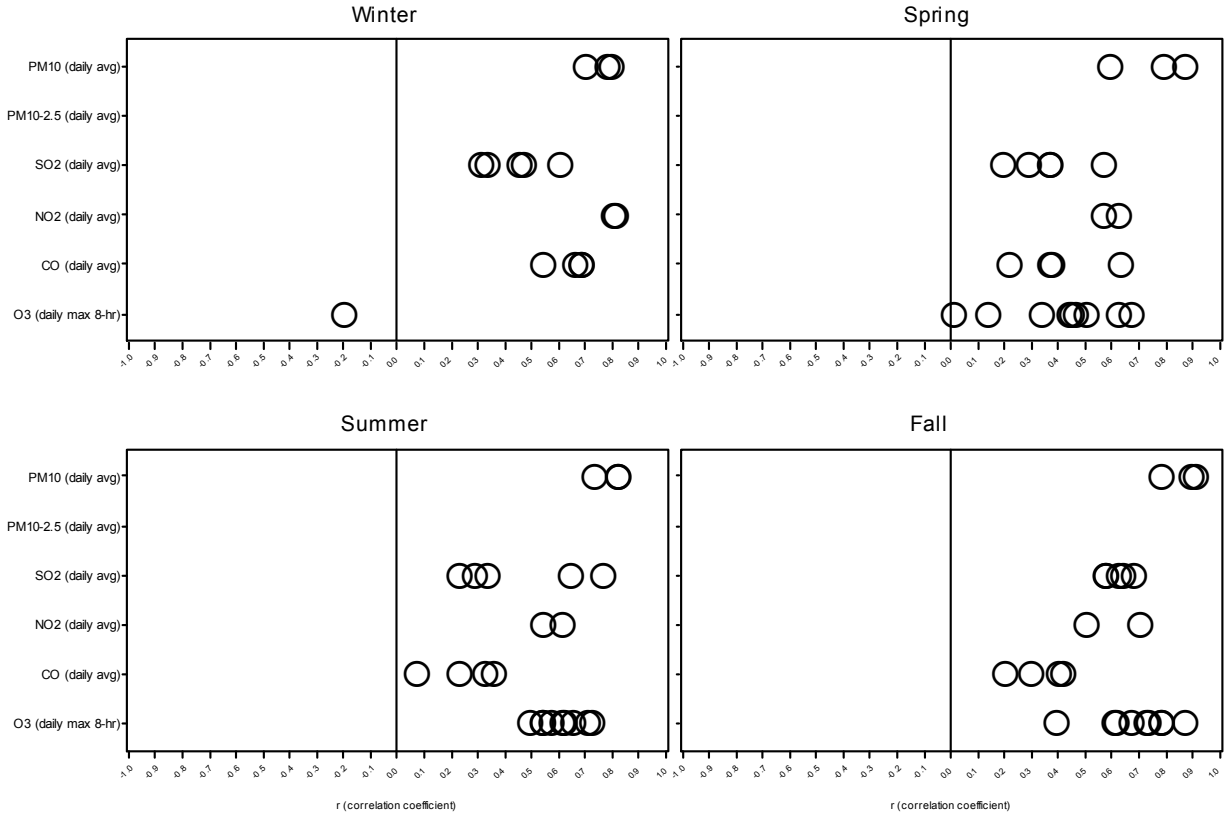

Figure A-180. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Detroit, MI, stratified by season (2005-2007). One point is included for each available monitor pair.

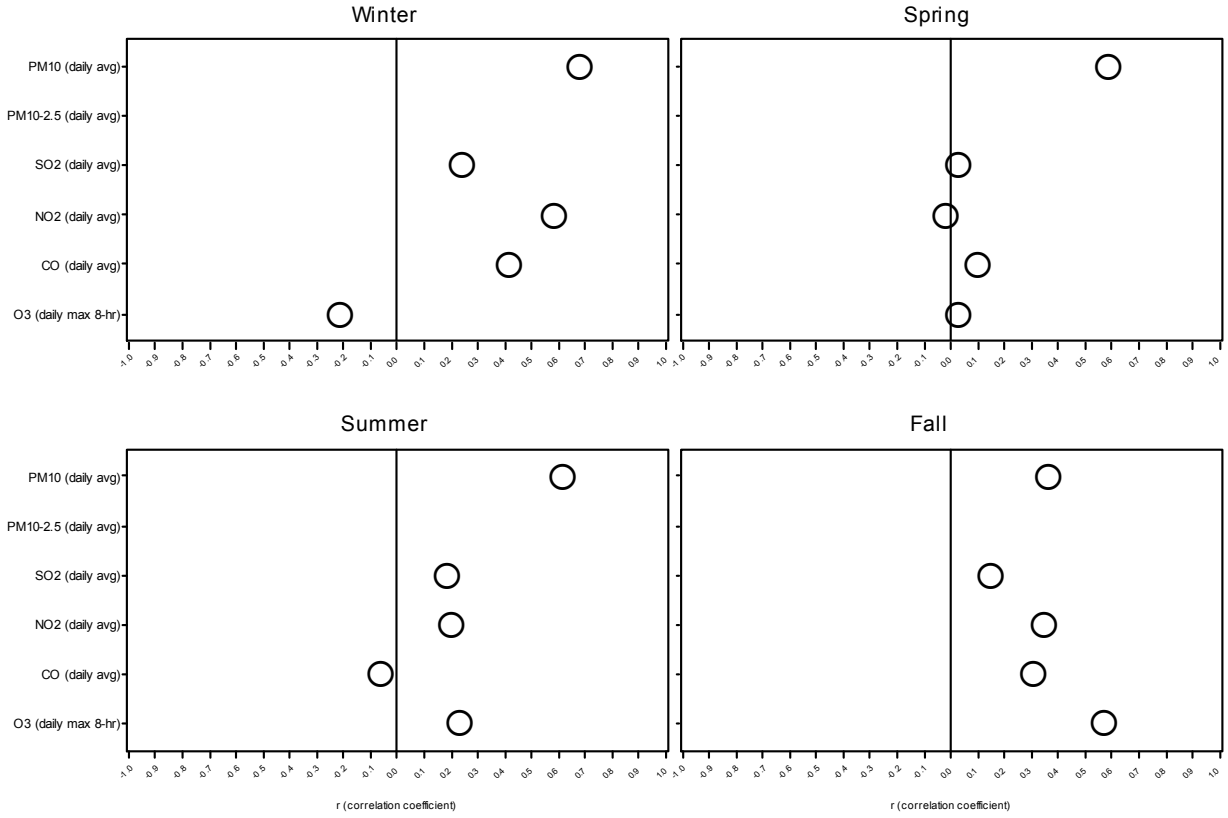

Figure A-181. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Houston, TX, stratified by season (2005-2007). One point is included for each available monitor pair.

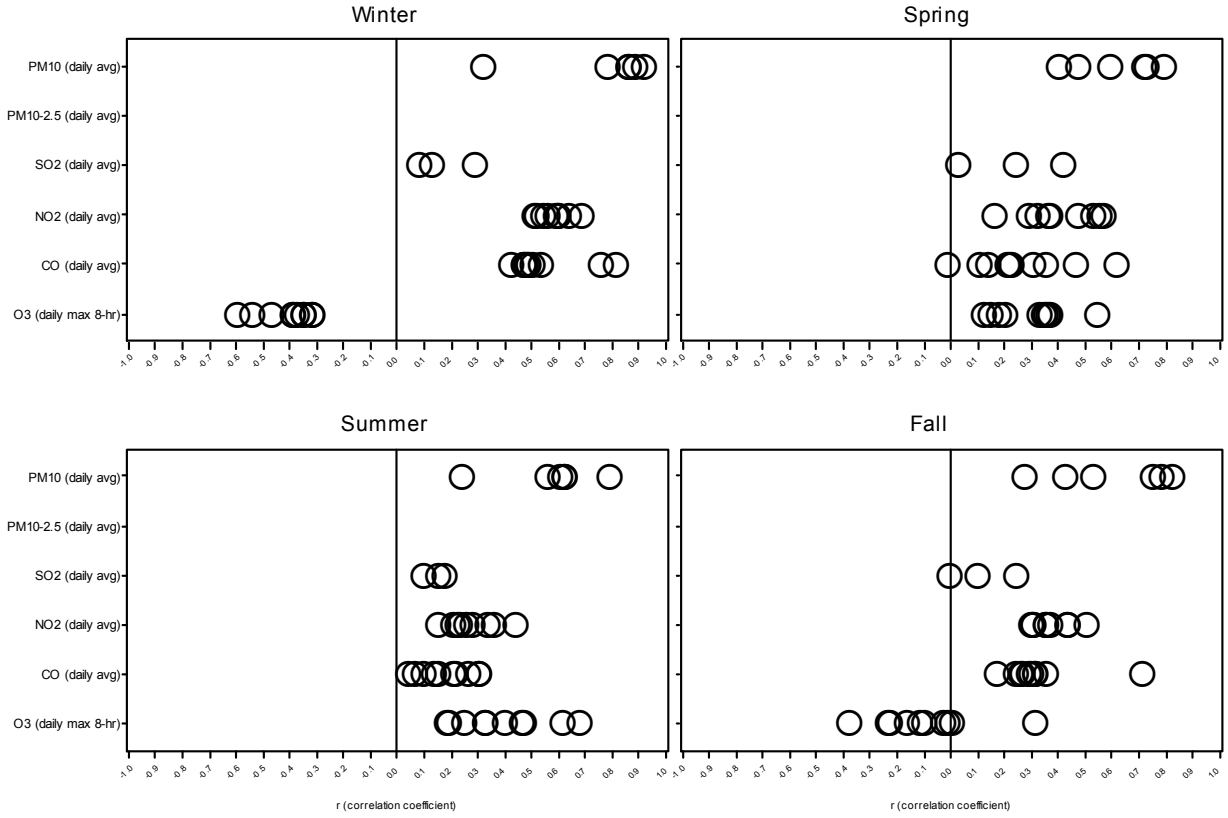

Figure A-182. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Los Angeles, CA, stratified by season (2005-2007). One point is included for each available monitor pair.

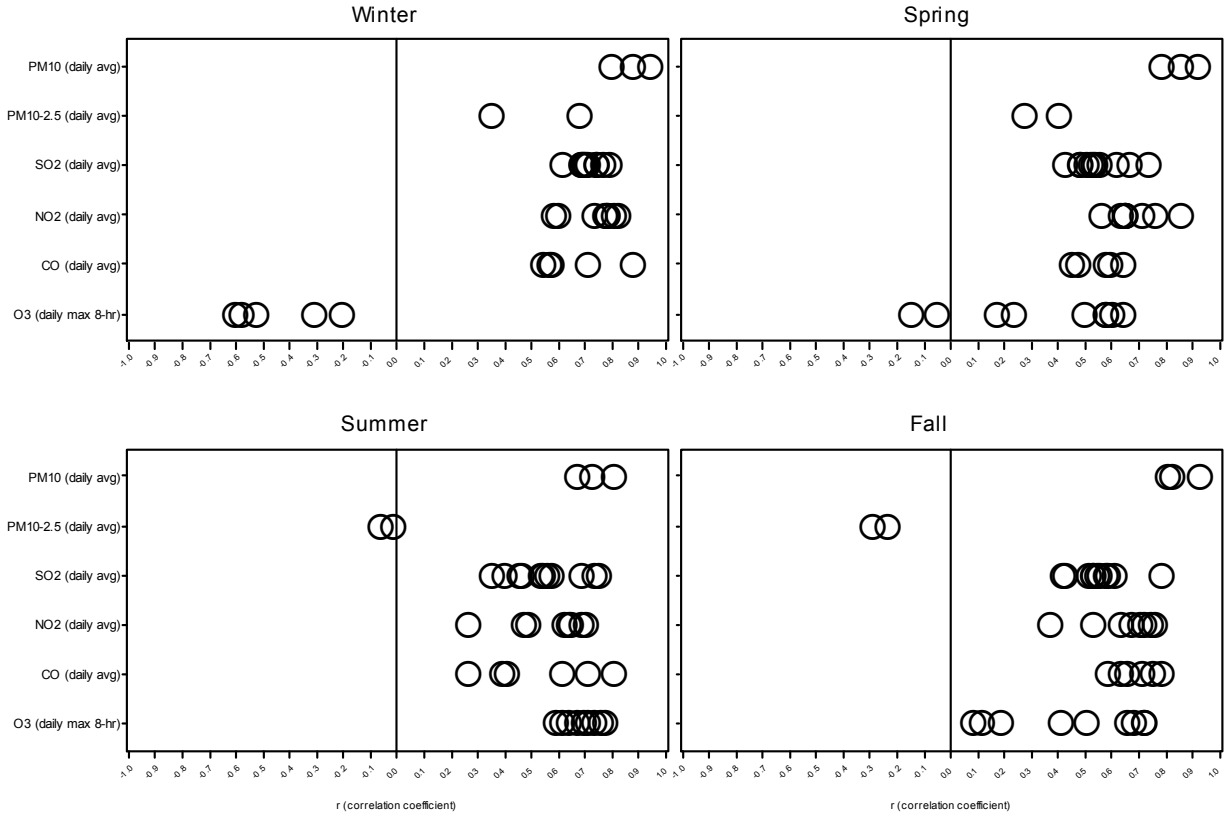

Figure A-183. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for New York, NY, stratified by season (2005-2007). One point is included for each available monitor pair.

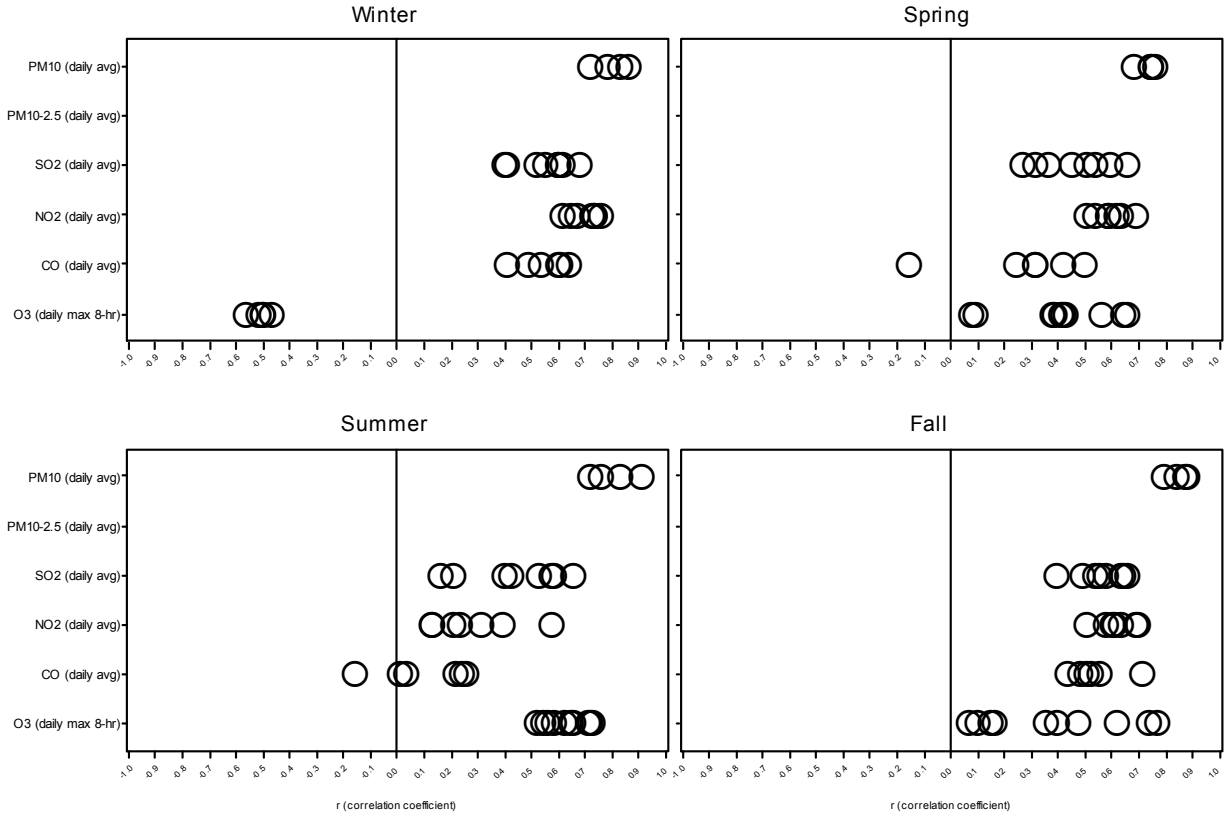

Figure A-184. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Philadelphia, PA, stratified by season (2005-2007). One point is included for each available monitor pair.

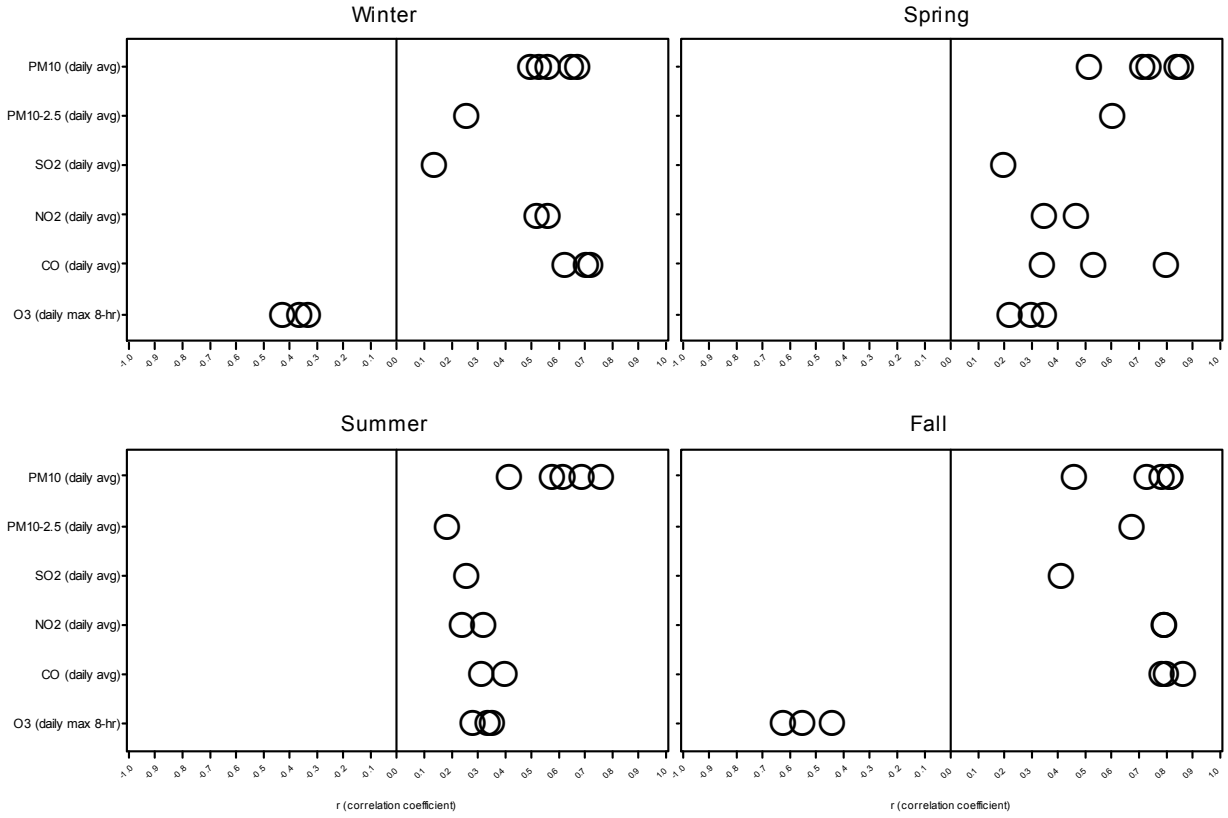

Figure A-185. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Phoenix, AZ, stratified by season (2005-2007). One point is included for each available monitor pair.

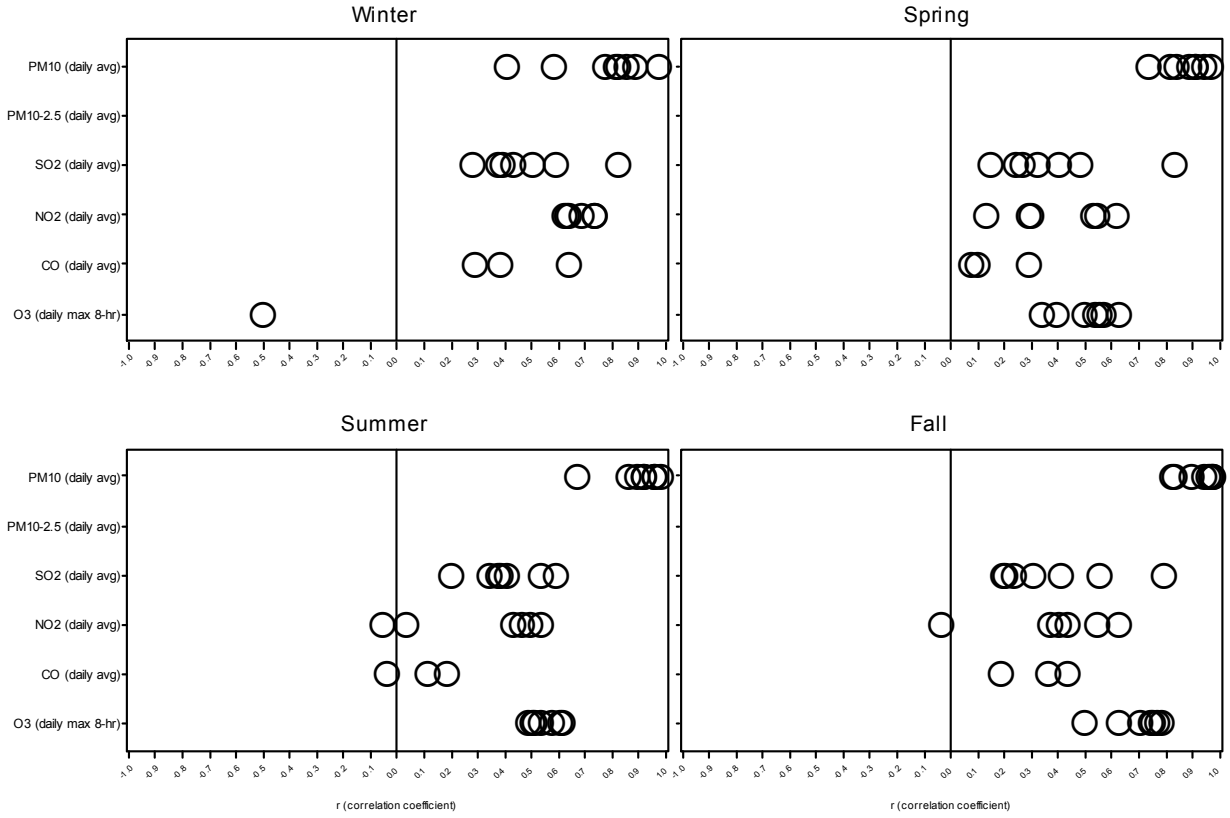

Figure A-186. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Pittsburgh, PA, stratified by season (2005-2007). One point is included for each available monitor pair.

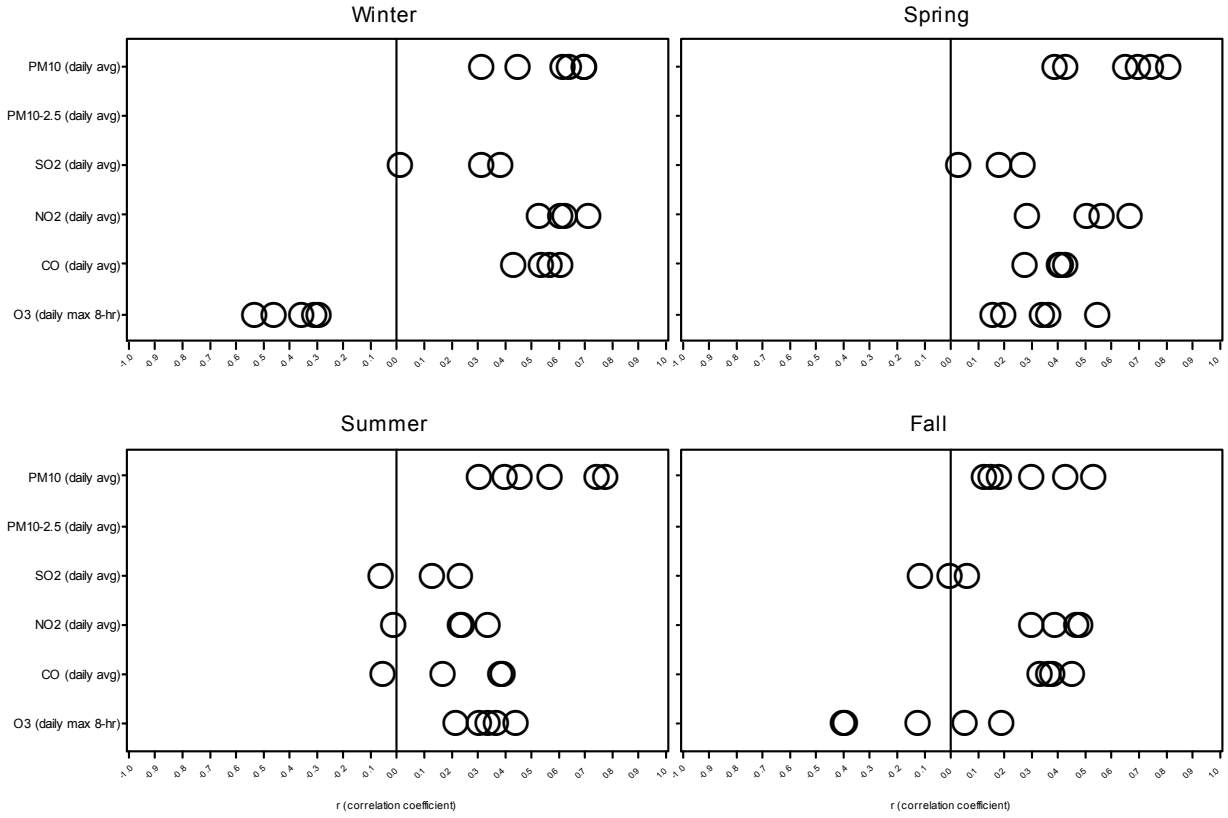

Figure A-187. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Riverside, CA, stratified by season (2005-2007). One point is included for each available monitor pair.

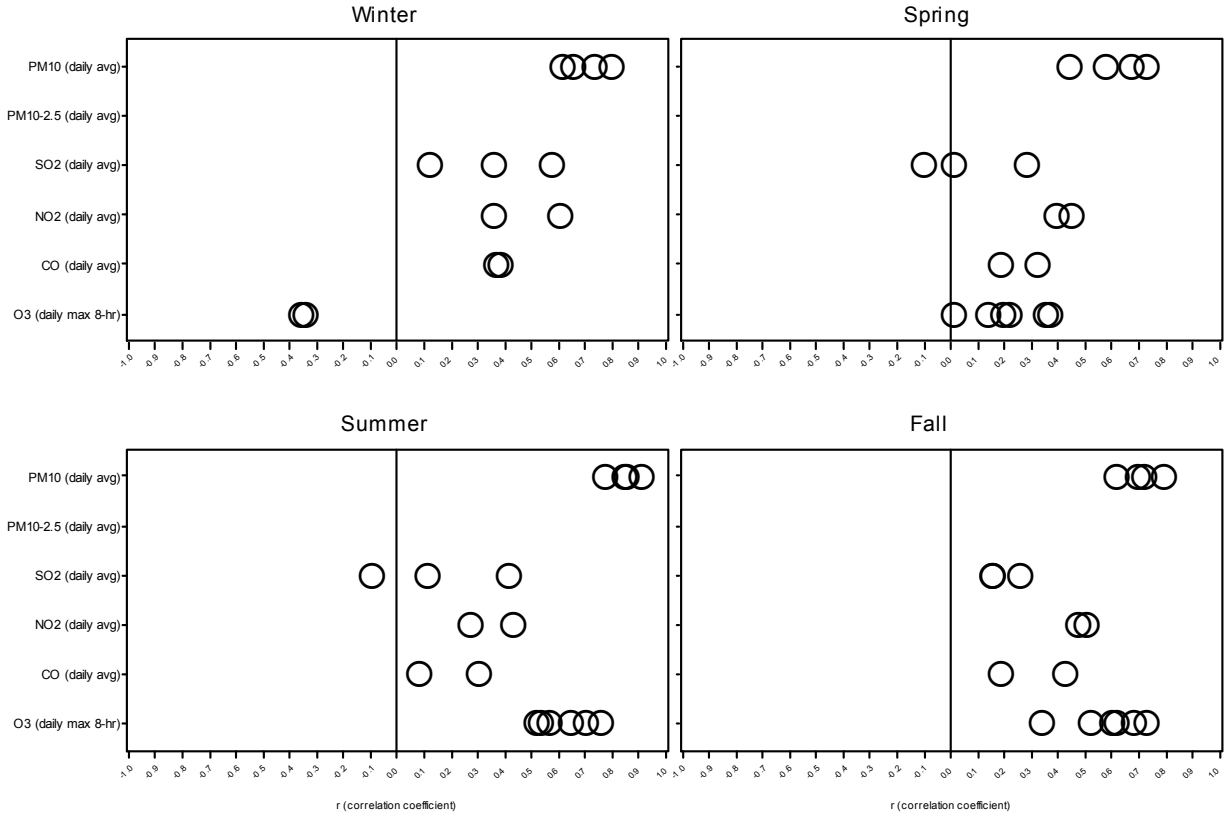

Figure A-188. Correlations between 24-h $PM_{2.5}$ and co-located 24-h avg PM_{10}, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for St. Louis, MO, stratified by season (2005-2007). One point is included for each available monitor pair.

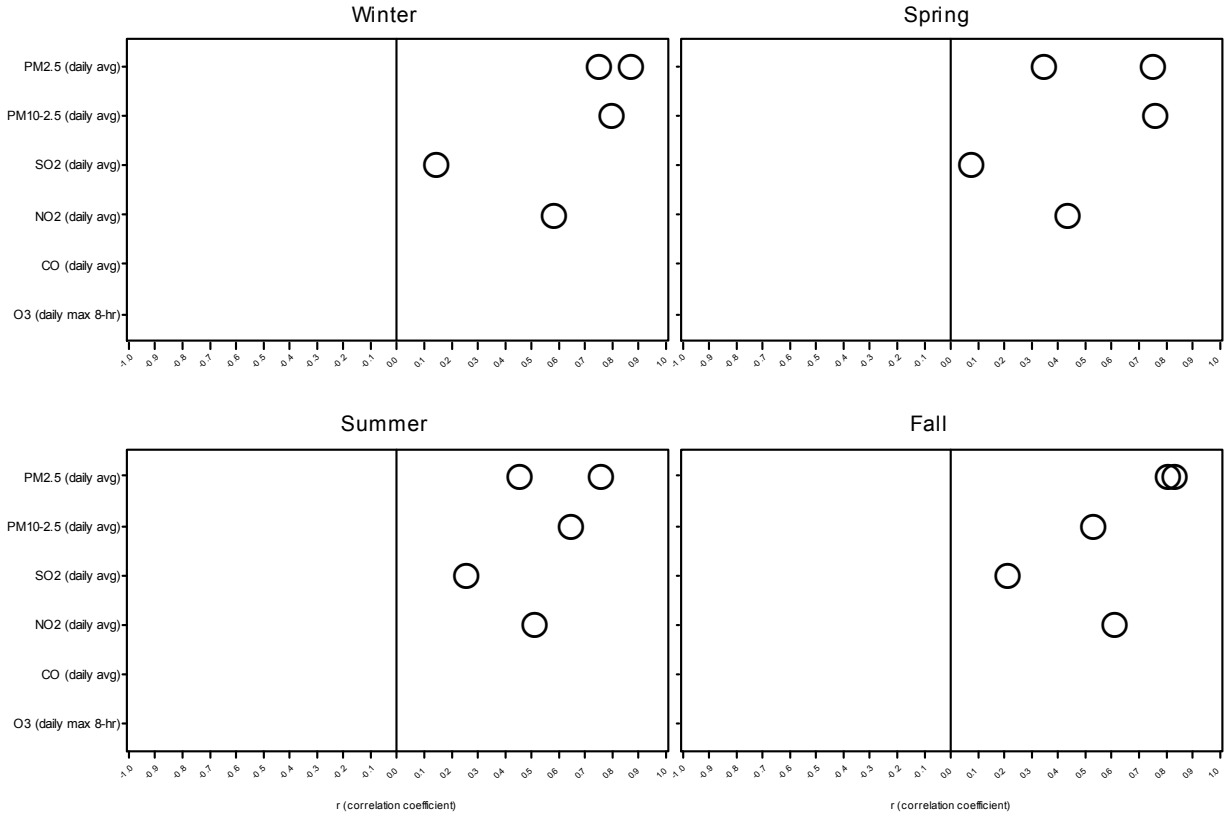

Figure A-189. Correlations between 24-h PM_{10} and co-located 24-h avg $PM_{2.5}$, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Atlanta, GA, stratified by season (2005-2007). One point is included for each available monitor pair.

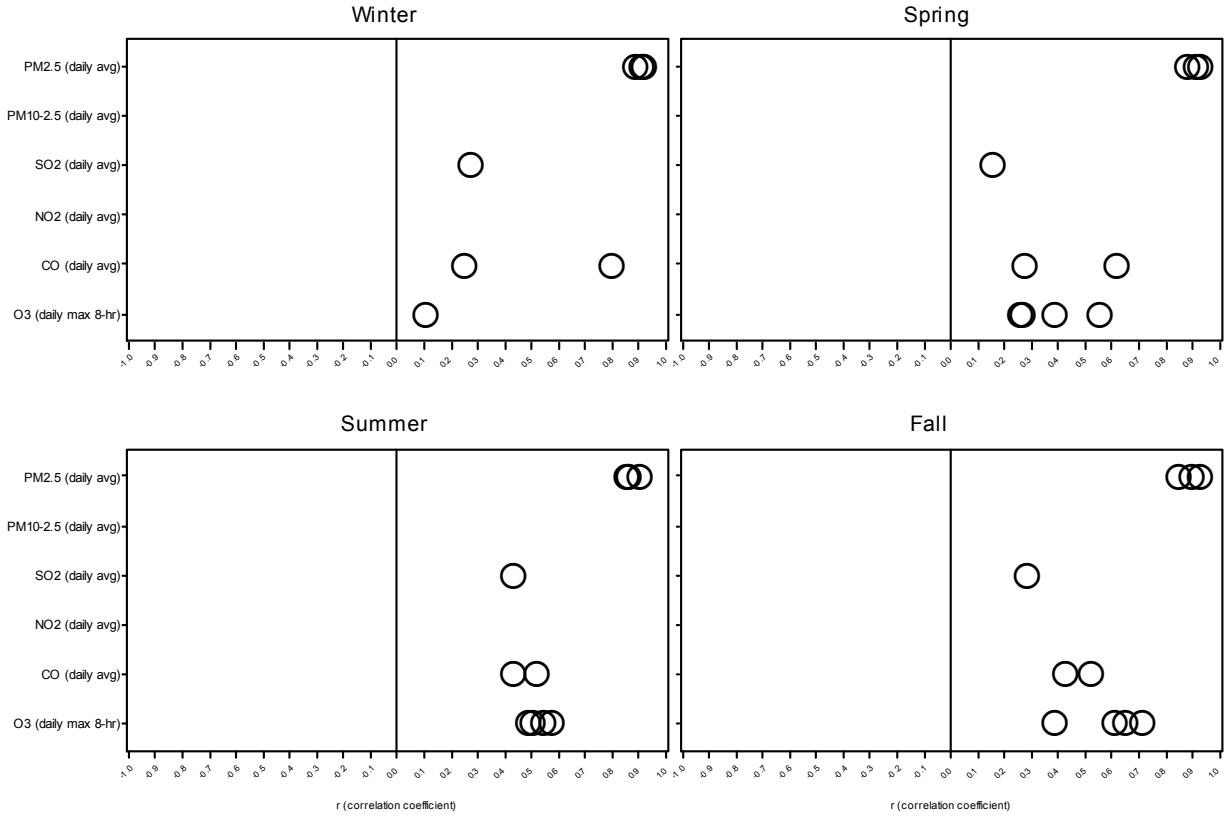

Figure A-190. Correlations between 24-h PM_{10} and co-located 24-h avg $PM_{2.5}$, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Birmingham, AL, stratified by season (2005-2007). One point is included for each available monitor pair.

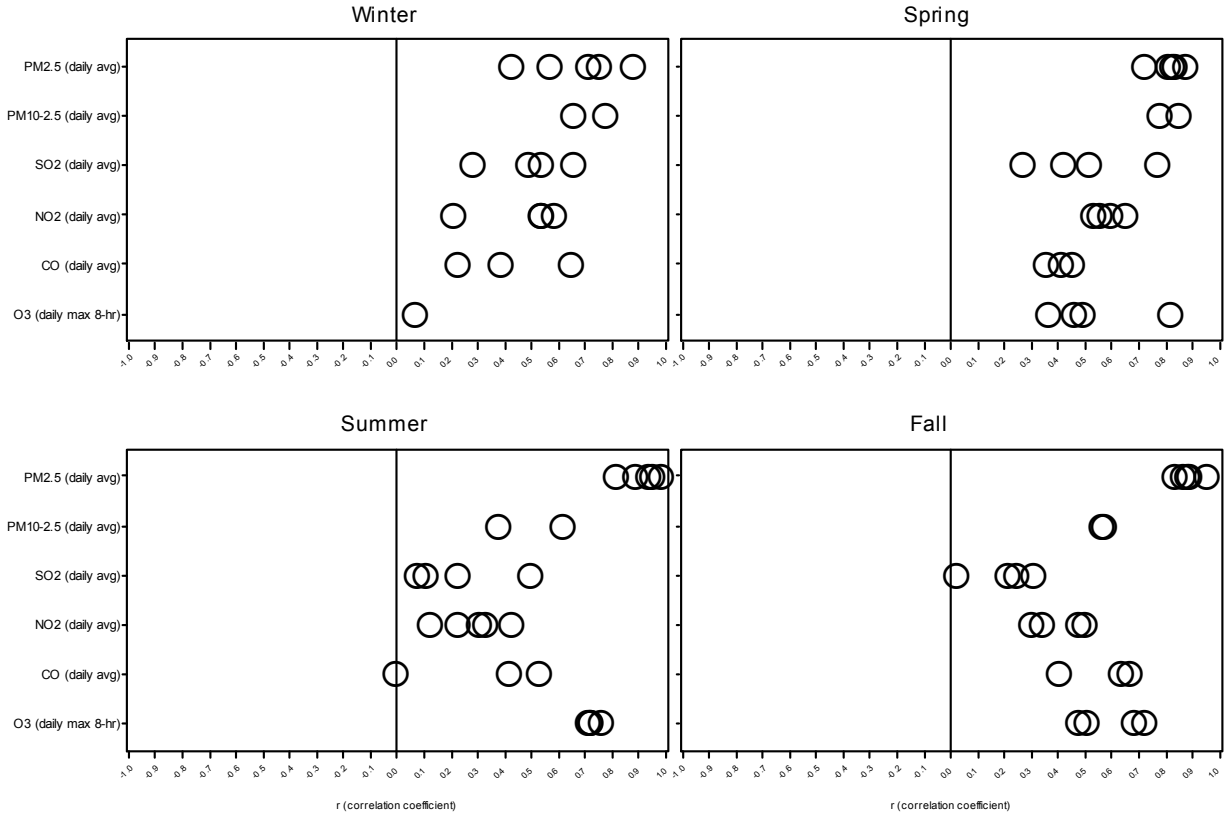

Figure A-191. Correlations between 24-h PM_{10} and co-located 24-h avg $PM_{2.5}$, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Boston, MA, stratified by season (2005-2007). One point is included for each available monitor pair.

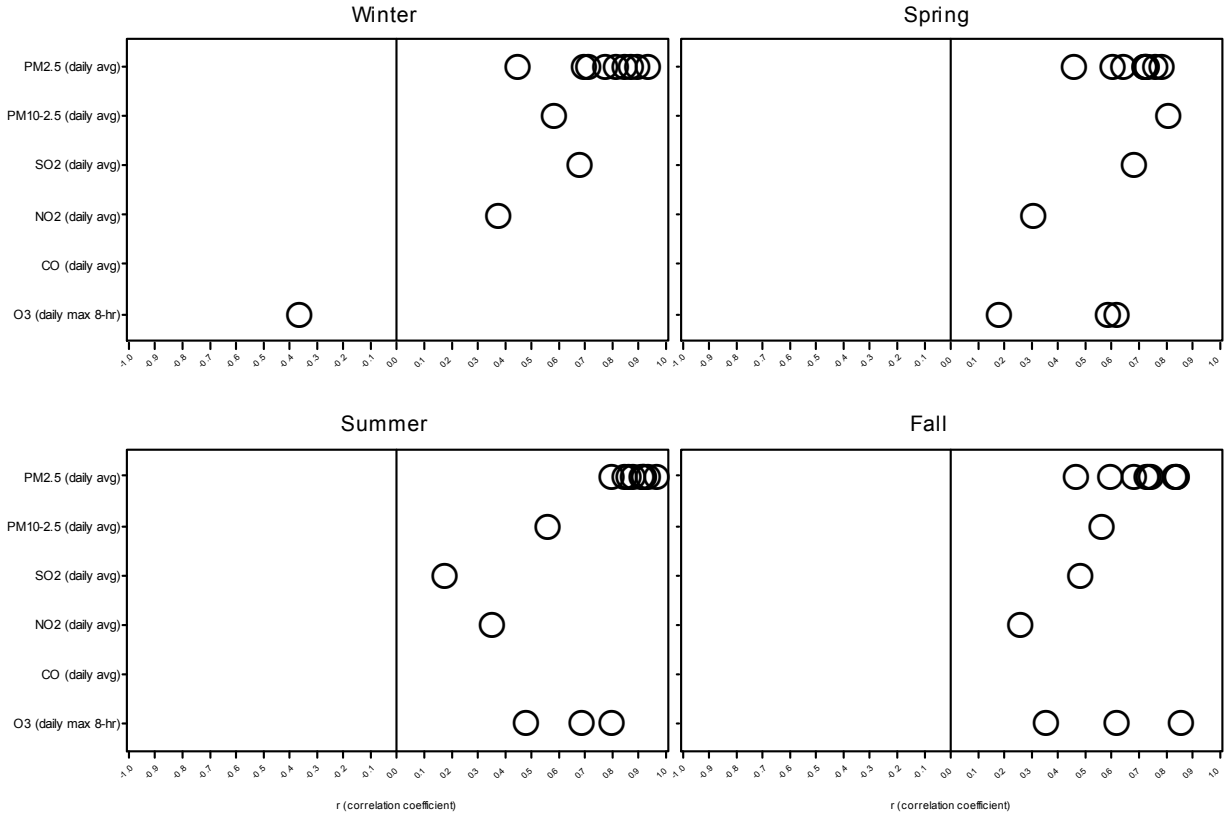

Figure A-192. Correlations between 24-h PM_{10} and co-located 24-h avg $PM_{2.5}$, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Chicago, IL, stratified by season (2005-2007). One point is included for each available monitor pair.

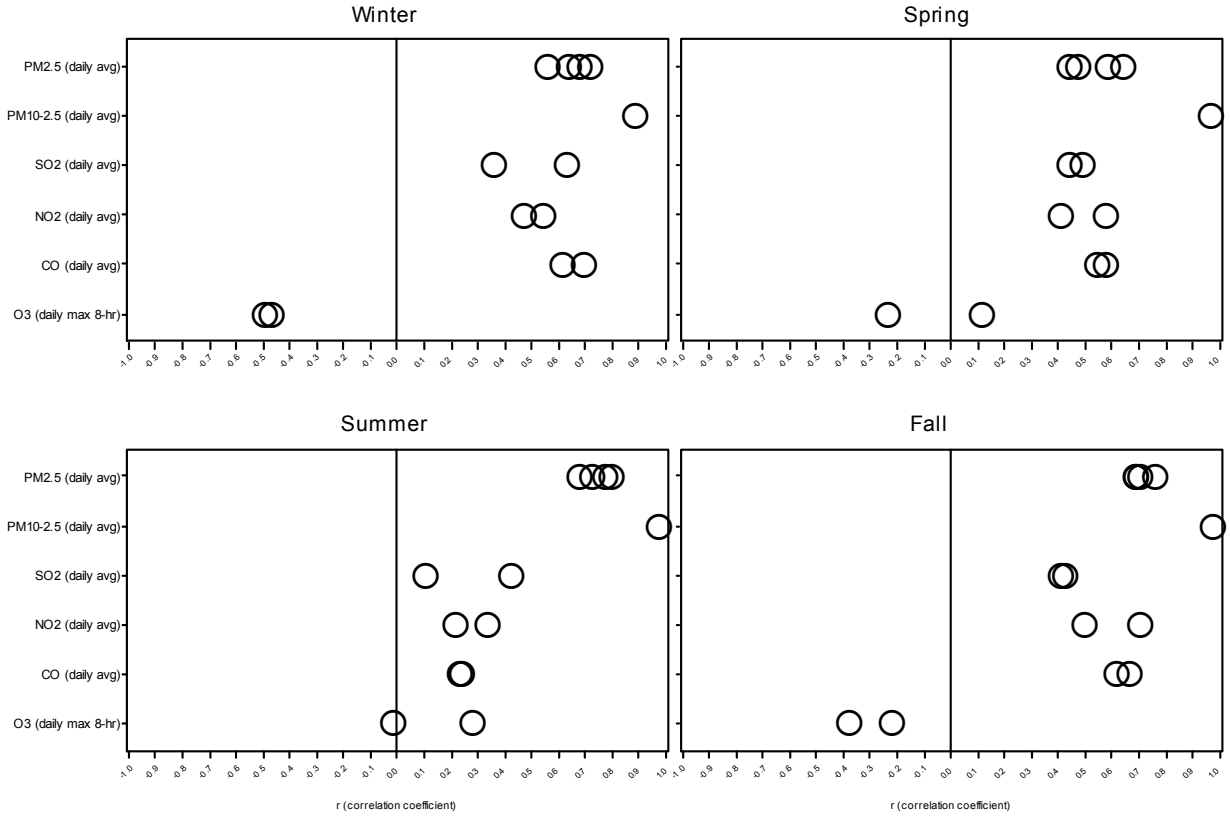

Figure A-193. Correlations between 24-h PM_{10} and co-located 24-h avg $PM_{2.5}$, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Denver, CO, stratified by season (2005-2007). One point is included for each available monitor pair.

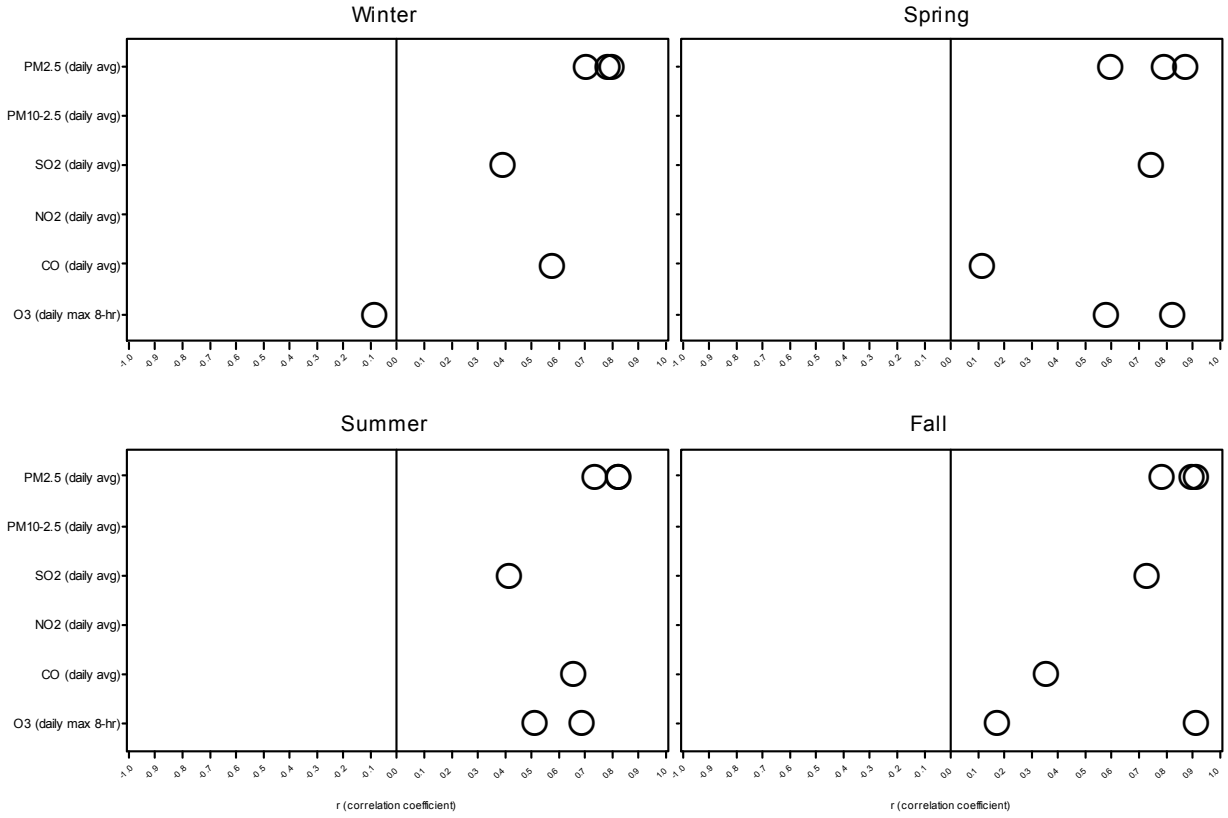

Figure A-194. Correlations between 24-h PM_{10} and co-located 24-h avg $PM_{2.5}$, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Detroit, MI, stratified by season (2005-2007). One point is included for each available monitor pair.

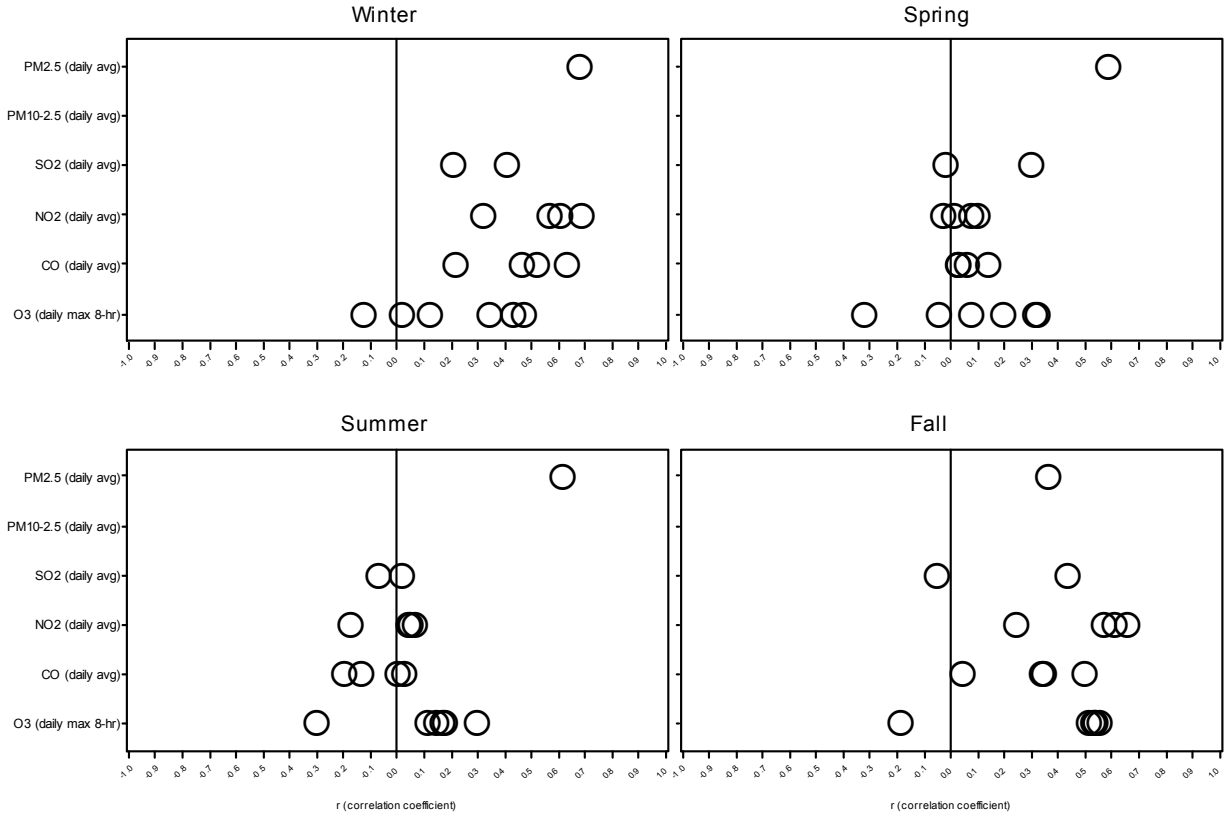

Figure A-195. Correlations between 24-h PM_{10} and co-located 24-h avg $PM_{2.5}$, $PM_{10-2.5}$, SO_2, NO_2 and CO and daily maximum 8-h avg O_3 for Houston, TX, stratified by season (2005-2007). One point is included for each available monitor pair.

A.3. Source Apportionment

A.3.1. Type of Receptor Models

Table A-51. Different receptor models used in the Supersite source apportionment studies: chemical mass balance.

Receptor Model	Description	Strengths and Weaknesses
Effective Variance CMB [42,121] (Note that all models based on eq 1 or 2 are CMB equations. The term CMB used here reflects the historical solution in which source profiles are explicitly used as model input and a single sample effective variance solution is reported.) CMB software is currently distributed by EPA. The most recent version is the CMB 8.2, which is run in the Microsoft Windows system.	**Principle** Ambient chemical concentrations are expressed as the sum of products of species abundances in source emissions and source contributions (Equations A-1 or A-2). These equations are solved for the source contribution estimates when ambient concentrations and source profiles are input. The single-sample effective variance least squares is the most commonly used solution method because it incorporates uncertainties of ambient concentrations and source profiles in the estimate of source contributions and their uncertainties. This reduced to the tracer solution when it is assumed that there is one unique species for each source. Choices of source profiles should avoid collinearity, which occurs when chemical compositions of various source emissions are not sufficiently different.[121] $$C_{iklmn} = \sum_{j=1}^{J} F_{ijm} T_{ijklmn} S_{iklmn}$$ **for i = 1 to I** **Equation A-1** $$C_{it} = \sum_{j} F_{ij} S_{jt} + E_{it}$$ **Equation A-2** **Data Needs** CMB requires source profiles, which are the mass fractions of particulate or gas species in source emissions. The species and particle size fraction measured in source emissions should match those in ambient samples to be apportioned. Several sampling and analysis methods provide time-integrated speciation of $PM_{2.5}$ and volatile organic compounds (VOCs) for CMB. Source profiles are preferably obtained in the same geographical region as the ambient samples, although using source profiles from different regions is commonly practiced in the literature. The practitioner needs to decide the source profiles and species being included in the model, on the basis of the conceptual model and model performance measures. **Output** Effective variance CMB determines, if converged, source contributions to each sample in terms of PM or VOC mass. CMB also generates various model performance measures, including correlation R^2, deviation X^2, residue/ uncertainty ratio, and MPIN matrix that are useful for refining the model inputs to obtain the best and most meaningful source apportionment resolution.	**Strengths** Software available providing a good user interface. Provides quantitative uncertainties on source contribution estimates based on input concentrations, measurement uncertainties, and collinearity of source profiles. Quantifies contributions from source types with single particle and organic compound measurements. **Weaknesses** Completely compatible source and receptor measurements are not commonly available. Assumes all observed mass is due to the sources selected in advance, which involves some subjectivity. Chemically similar sources may result in collinearity without more specific chemical markers. Typically does not apportion secondary particle constituents to sources. Must be combined with profile aging model to estimate secondary PM.

Table A-52. Different receptor models used in the Supersites source apportionment studies: factor analysis.

Receptor Model	Description	Strengths and Weaknesses
PMF PMF_x (PMF_2 and PMF_3) software is available from Dr. Pentti Paatero at the University of Helsinki, Finland. This software is a Microsoft DOS application. EPA distributes EPA PMF76 version 1.1 as a Microsoft Windows application with better user interface.	**Principle** PMFx contains PMF_2 and PMF_3. PMF_2 solves the CMB equations (i.e., Equations A-2 and A-3) using an iterative minimization algorithm. Source profiles F_{ij} and contribution S_{jt} are solved simultaneously. The non-negativity constraint is implemented in the algorithm to decrease the number of possible solutions (local minimums) in the PMF analyses, because both source profile and contribution should not contain negative values. There is rotational ambiguity in all two-way factor analyses (i.e.,F_{jt} and S_{jt} matrices may be rotated and still fit the data). PMF2 allows using the FPEAK parameter to control the rotation. A positive FPEAK value forces the program to search such solutions where there are many zeros and large values but few intermediate values in the source matrix $F_{jt}.F_{key}$ can further bind individual elements in F_{jt} to zero On the basis of a similar algorithm, PMF3 solves a three-way problem. PMFx and UNMIX estimate F_{ij} and S_{jt} by minimizing: $$Q \text{ or } \chi^2 = \sum_i \sum_t [E_{it}/\sigma_{it}]^2 = \sum_i \sum_t [(C_{it} - \sum_j F_{ij} S_{jt})/\sigma_{it}]^2 \quad \textbf{Equation A-3}$$ Where the weighing factor, σit, represents the magnitude of Eit, PMFx limits solutions of Equation A-2 to non-negative F_{ij} and S_{jt}. **Data Needs** A large number of ambient samples (usually much more than the number of factors in the model) are required to produce a meaningful solution. Species commonly used in PMF are also those in CMB. Weighting factors associated with each measurement need to be assigned before analysis. The practitioner also needs to decide the number of factors, FPEAK, and Fkey in the model. **Output** PMFx reports all the elements in F_{ij} and S_{jt} matrices (PMF2). It also calculates model performance measures such as deviation X^2 and standard deviation of each matrix element. The practitioner needs to interpret the results linking them to source profiles and source contributions.	**Strengths** Software available. Can handle missing or below-detection-limit data. Weights species concentrations by their analytical precisions. Downweight outliers in the robust mode. Derives source profiles from ambient measurements as they would appear at the receptor (does not require source measurements). **Weaknesses** Requires large (>100) ambient datasets. Need to determine the number of retaining factors. Requires knowledge of source profiles or existing profiles to verify the representativeness of calculated factor profiles and uncertainties of factor contributions. Relies on many parameters/initial conditions adjustable to model input; sensitive to the preset parameters.
ME2[125] ME2 code is available from Dr. Pentti Paatero at the University of Helsinki, Finland as a Microsoft DOS application.	**Principle** The PMFx algorithm is derived from ME2. Unlike PMFx that is limited to questions in the form of Equation A-1 or A-2, ME2 solves all models in which the data values are fitted by sums of products of unknown (and known) factor elements. The first part of the algorithm interprets instructions from the user and generates a table that specifies the model. The second part solves the model using an iterative minimization approach. Additional constraints could be programmed into the model to reduce the ambiguity in source apportionment. These constraints may include known source profiles and/or contributions (e.g., contributions are known to be zero in some cases). **Data Needs** Data needs are similar to those of PMFx but are more flexible. In theory, any measured or unknown variables may be included in the model as long as they satisfy linear relationships. The users need to specify the model structure, the input, and the output. **Output** ME2 calculates and reports all unknown variables in the model.	**Strengths** Software available. Can handle user-specified models. Possibility to include all measured variables into the model, such as speciated concentration over different time scales, size distributions, meteorological variables, and noise parameters. **Weaknesses** Require substantial training to access the full feature of the software and develop a model. Generally requires large ambient datasets. Need to assume linear relationships between all variables. Relies on many parameters/initial conditions adjustable to model input; sensitive to the preset parameters.

Receptor Model	Description	Strengths and Weaknesses
UNMIX [29,44,126] UNMIX code is available from Dr. Ron Henry at the University of Southern California as an MatLab application. A stand-alone version (UNMIX version 6) is also available from EPA.	**Principle** UNMIX views each sample as a data point in a multidimensional space with each dimension representing a measured species. UNMIX solves Equations A-2 and A-3 by using a principle component analysis (PCA) approach to reduce the number of dimensions in the space to the number of factors that produce the data, followed by an unique "edge detection" technique to identify "edges" defined by the data points in the space of reduced dimension (e.g., Figures 1 and 3). The number of factors is estimated by the NUMFACT algorithm in advance[127], which reports the R^2 and signal-to-noise (S/N) ratio associated with the first N principle components (PCs) in the data matrix. The number of factors should coincide with the number of PCs with S/N ratio >2. Once the data are plotted on the reduced space, an edge is actually a hyperplan that signifies missing or small contribution from one or more factors. Therefore, UNMIX searches all the edges and uses them to calculate the vertices of the simplex, which are then converted back to source composition and contributions. Geometrical concepts of self-modeling curve resolution are used to ensure that the results obey (to within error) non-negativity constraints on source compositions and contributions. **Data Needs** A large number of ambient samples (usually much more than the number of factors in the model) are required to achieve a meaningful solution. Species commonly used in UNMIX are also those in CMB. The measurement precision is not required. The practitioner needs to specify the number of factors on the basis of the NUMFACT results. **Output** UNMIX determines all the elements in the factor (F_{ij}) and contribution (S_{it}) matrices. It also calculates the uncertainty associated with the factor elements and model performance measures including: (1) R^2, (2) S/N ratio, and (3) strength.	**Strengths** Software available with graphical user interface. Does not require source measurements. Provide graphical problem diagnostic tools (e.g., species scatter plot). Provide evaluation tools (e.g., R^2, S/N ratio). **Weaknesses** Requires large (>100) ambient datasets. Need to assume or predetermine number of retained factors. Does not make explicit use of errors or uncertainties in ambient measurements. Cannot use samples containing missing data in any species. Limited to a maximum of 7 or 14 (UNMIX version 6) factors. Can report multiple or no solutions. Requires knowledge of existing source profiles to evaluate the solutions.

Receptor Model	Description	Strengths and Weaknesses
PDRM[97] PDRM was developed under the Supersites Program and requires MatLab or equivalent software to perform the calculation.	**Principle** PDRM estimates contributions from selected stationary sources for a receptor site using high time-resolution measurements and meteorological data. In PDRM, Equation A-2 is modified to: $$C_k = \sum_j ER_{ij}\left(\frac{\chi}{Q}\right)_{j,t} + E_k$$ **Equation A-4** where $ER_{i,j}$ is interpreted as the emission rate of species i from stationary source j and (X/Q,t is the meteorological dispersion factor averaged over the time interval t. Equation A-4 is solved for ERi,j and (X/Q,t simultaneously by a nonlinear fit minimizing the objective function, FUN: $$FUN = \sum_{i=1}^{l}\sum_{t=1}^{m}\sum_{j=1}^{n}\left[ER_{ij}\left(\frac{\chi}{Q}\right)_{j,t}^{PDRM} - C_k\right]^2$$ **Equation A-5** Because the number of solutions for a product of unknowns is infinite, additional constraints are set up for (X/Q,t on the basis of the Gaussian plume model, thus: $$LB\left(\frac{\chi}{Q}\right)_{j,t}^{Met} \le \left(\frac{\chi}{Q}\right)_{j,t}^{PDRM} \le UB\left(\frac{\chi}{Q}\right)_{j,t}^{Met}$$ $$\left(\frac{\chi}{Q}\right)_{j,t}^{Met} = \frac{1}{2\pi\sigma_y\sigma_z u}\exp\left(-\frac{1}{2}\frac{y^2}{\sigma_y^2}\right)\left\{\exp\left[-\frac{1}{2}\left(\frac{z-h}{\sigma_z}\right)^2\right] + \exp\left[-\frac{1}{2}\left(\frac{z+h}{\sigma_z}\right)^2\right]\right\}$$ **Equations A-6 & A-7** Equations A-6 and A-7 limit the solution of Equation A-5 within the lower (LB) and upper (UB) bound of those predicted by the Gaussian plume model using different parameterizations. **Data Needs** PDRM requires speciated measurements at a higher time-resolution than typical CMB or PMF applications because of the fast-changing meteorological parameters. PDRM also requires data for Equation A-7: transport speed (u), lateral and vertical dispersion parameters (σy and σz), and stack height (h). **Output** PDRM determines emission rates and contributions from each point source considered in the model at the same time resolution as the measurement.	**Strengths** Explicitly include meteorological information and stack configuration of stationary sources into the model. Do not require source measurements. Do not need to interpret the relations between factors and sources. Commercial software (e.g., MatLab) available for performing nonlinear fit. Suitable for high time-resolution measurement. **Weaknesses** Can only handle stationary sources but not area or mobile sources. Need to assume that only stationary sources are considered in the model contribute significantly for a measurement at the receptor site. Do not account for uncertainty in the measurement. Meteorological data may not be always available or accurate. Gaussian plume model may not be representative of the actual atmospheric dispersion. Sensitive to the imposed constraints (UB and LB).

Receptor Model	Description	Strengths and Weaknesses
PLS[128]	**Principle** PLS examines the relationships between a set of predictor (independent) and response (dependent) variables. It assumes that the predictor and response variables are controlled by independent "latent variables" less in number than either the predictor or the response variables. In recent applications, [96] PM chemical composition and size distribution are used as predictor (X) and response (Y) variables, respectively. Equation A- 2 is modified to: $$X_k = \sum_i T_i P_{ik} + E_k$$ **Equation A-8** $$Y_n = \sum_i U_i C_{in} + D_k$$ **Equation A-9** where T and U are matrices of so-called "latent variables," and P and C are loading matrices. If X and Y are correlated to some degree, T and U would show some similarity. Equations A-8 and A-9 are solved by an iterative algorithm "NIPALS," which attempts to minimize E,D, and the difference between T and U simultaneously. If T and U end up being close enough, the X and Y variables can be explained by the same latent variables. These latent variables may then be interpreted as source or source categories. **Data Needs** Typical applications of PLS require both chemical speciated and size-segregated measurements. The practitioner needs to decide the number of latent variables on the basis of the correlation of resulting T and U matrices. **Output** PLS calculates latent variables, which are common factors best explaining the predictor and response variables, and the residues from fitting. Rx and Ry, $$R_x = 1 - \text{var}(E)/\text{var}(X)$$ **Equation A-10** $$R_y = 1 - \text{var}(D)/\text{var}(Y)$$ **Equation A-11** indicate the degree to which variables X and Y are explained by the latent variables.	**Strengths** Fit two types of measurements (e.g., chemistry and size) with common factors. Provide more information to identify sources. Analyze strongly collinear and noisy dataset. Do not require source measurements. **Weaknesses** Requires large (>100) ambient datasets. Difficult to relate latent variables to any physical quantities. Do not provide quantitative source contribution estimates. Need to decide the number of latent variables. Do not explicitly make use of measurement uncertainties. Can result in no solution.

Table A-53. Different receptor models used in the Supersites source apportionment studies: tracer-based methods.

Receptor Model	Description	Strengths and Weaknesses
EF [129,130] The EF method may use a MLR algorithm, which is available in most statistical and spreadsheet software	**Principle** A tracer (or marker) for a particular source or source category is a species enriched heavily in the source emission against other species and other sources. Using EFs-, concentration of the ith pollutant at a receptor site at time t (i.e., Ci,t) can be expressed as: $$C_{i,t} = \sum_{j} \frac{1}{EF_{i,pj}} C_{pj,t} + Z_{i,t} = \sum_{j} \left(\frac{F_{ij}}{F_{pj}}\right) C_{pj,t} + Z_{i,t}$$ **Equation A-12** where the enrichment factor $EF_{i,pj}$ is the ratio of emission rate of the pollutant of interest (F_{ij}) and tracer species (F_{pj}) from source j. $C_{pj,t}$ is the concentration of tracer species for source j at time t, and Zi,t represents contributions from all other sources (including the background level). The solution for eq 12 is situation-dependent. $EF_{i,pj}$ is usually unknown but may be estimated from source profiles, edges of a two-way scatter plot or the ratio of $C_{i,t}$ to $C_{pj,t}$ for a particular period when it is believed that a single source is dominant. In cases where $Z_{i,t}$ is a constant, $EF_{i,pj}$ may be derived from MLR. **Data Needs** The minimum data needs include concentrations of all primary tracers at the receptor site. Known EFs or background levels are helpful. **Output** The EF method determines contributions to species i from each source considered in the model.	**Strengths** No special software needed. Indicate presence or absence of particular emitters. Provides evidence of secondary PM formation and changes in source impacts by changes in ambient composition. Could use a large (>100) dataset or a small (e.g., < 10) dataset. **Weaknesses** Semiquantitative method, not specific especially when the EFs are unknown in advance. Limited to sources with unique markers. Tracer species must be exclusively from the sources or source categories examined. Provide very limited error estimates. More useful for source/process identification than for quantification.
NNLS [131,132] The MatLab Optimization Toolbox provides a function "lsqnonneg" for performing the NNLS calculation.	**Principle** NNLS also solves the EF equation (Equation A-12 or equivalent) with known target species and tracer concentrations. Conventional MLR solutions to eq 12 may lead to negative EFs due to the uncertainty in measurements or colinearity in source contributions. This is avoided in the NNLS approach since additional non-negative constraints are built into the algorithm, i.e.: $$EF_{i,pj} \geq 0$$ **Equation A-13** Utilizing orthogonal decomposition, a NNLS problem can be reduced to the more familiar least-distance programming and solved by a set of iterative subroutines developed and tested by Lawson and Hanson.131 In a more general sense, NNLS linearly relates a response variable to a set of independent variables with only non-negative coefficients. **Data Needs** When applied to EF or MLR problems, NNLS requires the concentration of target (response) and tracer (independent) species. **Output** NNLS generates non-negative regression coefficients for an EF/MLR problem and these coefficients can be related to the source contributions.	**Strengths** Implemented by many statistical software packages. Generate only non-negative EFs or regression coefficients. Do not require source measurements. Possible to include meteorological or other (besides chemistry) data into the model. **Weaknesses** Require a large (>100) set of ambient measurements. Semiquantitative method, not specific. Do not explicitly consider measurement uncertainties. Tracer species must be exclusively from the sources or source categories examined. Non-negative constraints may not be appropriate in some cases.

Receptor Model	Description	Strengths and Weaknesses
FAC	**Principle** FAC provides a simple mean of estimating the SOA production rate using the emission inventories of primary precursor VOCs. FAC is actually a source-oriented modeling technique but it does not take into account all the atmospheric processes. FAC is defined as the fraction of SOA that would result from the reactions of a particular VOC: $$[\text{SOA}] = \sum_i FAC_i \times ([\text{VOC}_i]_0 \times \text{Fraction of VOC } i \text{ reacted})$$ **Equation A-14** where $[\text{VOC}_i]_0$ is the emission rate of VOC_i and [SOA] is the formation rate of SOA. Equation A-14 can be viewed as an extension of Equation -12 but concentrations are replaced with emission rates and EFs are replaced with FACs. FAC and the fraction of VOC reacted under typical ambient conditions have been developed for a large number of hydrocarbons $>C_6$ [111]. The most significant SOA precursors are aromatic compounds (especially toluene, xylene, and trimethylbenzenes) and terpenes. In most applications, these FACs are used directly to estimate SOA. **Data Needs** FAC requires the VOC emission inventory in the region of interest. The knowledge of O_3 and radiation intensity is also helpful for slight modifications of the FACs. **Output** FAC method estimates the total production rate of SOA.	**Strengths** Link SOA to primary VOC emissions so that SOA can also be treated as primary particles in the PM modeling. Simple and inexpensive. **Weaknesses** Ignore the influence of aerosol concentration and temperature-dependent gas-particle partitioning on SOA yield. Limited by the accuracy of VOC emission inventory. Do not directly infer the contribution of each source to ambient SOA concentration. Difficult to verify.

Table A-54. Different receptor models used in the Supersites source apportionment studies: meteorology-based methods.

Receptor Model	Description	Strengths and Weaknesses
CPF [134,135]	**Principle** CPF estimates the probability that a given source contribution from a given wind direction will exceed a predetermined threshold criterion (e.g., upper 25th percentile of the fractional contribution from the source of interest). The calculation of CPF uses source contributions (i.e., O_3 in Equation A-2) determined for the receptor site and local wind direction data matching each of the source contributions in time. These data are then segregated to several sectors according to wind direction and the desired resolution (usually 36 sectors at a 10° resolution). Data with very low wind speed (e.g., < 0.1 m/sec) are usually excluded from analysis because of the uncertain wind direction. CPF is then determined by: $$CPF(\theta) = \frac{m_{\Delta\theta}}{n_{\Delta\theta}}$$ **Equation A-15** where $m\Delta\theta$ is the number of occurrences in the direction sector $\theta \rightarrow \theta + \Delta\theta$ that exceeds the specified threshold, and $n\Delta\theta$ is the total number of wind occurrences in that sector. Because wind direction is changing rapidly, high-time resolution measurements (e.g., minutes to hours) are preferred for a CPF analysis. If the calculated source contributions represent long-term averages, wind direction needs to be averaged over the same duration. In addition to source contribution, CPF can be applied directly to pollutant concentration measurements at a receptor site. **Data Needs** CPF requires the time series of source contributions at a receptor site, which is usually determined by CMB or factor analysis methods using speciated measurements at the site. CPF also requires wind direction and wind speed data averaged over the same time resolution as the sampling duration. **Output** CPF reports the probability of "high" contribution from a particular source or factor occurring within each wind direction sector. The results are often presented in a wind rose plot.	**Strengths** Infer the direction of sources or factors relative to the receptor site. Provide verification for the source identification made by factor analysis method. Easy to implement. **Weaknesses** Criterion for the threshold is subjective. Absolute source contribution (or fractional contribution) may be influenced by other factors besides wind direction (e.g., wind speed, mixing height). Local and near-surface wind direction only has a limited implication for long-range transport. Easy to be biased by a small number of wind occurrences in a particular sector. Work better for stationary sources than area or mobile sources.

Receptor Model	Description	Strengths and Weaknesses
NPR [136,137]	**Principle** NPR calculates the expected (averaged) source contribution as a function of wind direction following: $$S(\theta) = \frac{\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right) \times S_i}{\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right)}$$ **Equation A-16** where Wi is the wind direction for the ith sample and Si is the contribution from a specific source to that sample, determined from measurements at the receptor site. K is a weighting function called the kernel estimator. There are many possible choices for K. Henry et al.[136] recommend either Gaussian or Epanechnikov functions. The most important decision in NPR is the choice of the smoothing parameter Δθ. If Δθ is too large, S(θ) will be too smooth and meaningful peaks could be lost. If it is too small, S(θ) will have too many small, meaningless peaks. Δθ needs to be chosen according to the project-specific spatial distribution of sources. NPR also estimates the confidence intervals of S(θ) based on the asymptotic normal distribution of the kernel estimates, thus: $$\Delta S(\theta) = \frac{\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right) \times (S_i - S(\theta))^2}{\left(\sum_i K\left(\frac{\theta - W_i}{\Delta\theta}\right)\right)^2}$$ **Equation A-17** **Data Needs** NPR requires the same data as the CPF method, including the time series of source/factor contributions (or fractional contributions) at the receptor site and local wind direction data matching the sampling duration in time. **Output** NPR reports the distribution of source contribution as a function of wind direction and the confidence level associated with it.	**Strengths** Infer the direction of sources or factors relative to the receptor site. Provide verification for the source identification made by factor analysis method. Require no assumption about the function form of the relationship between wind direction and source contribution. Provide uncertainty estimates. Easy to implement. **Weaknesses** Choices for the kernel estimator and smoothing factor are subjective. Absolute source contribution (or fractional contribution) may be influenced by other factors besides wind direction (e.g., wind speed, mixing height). Local and near-surface wind direction only has a limited implication for long-range transport. Easy to be biased by a small number of wind occurrences in a particular sector. Work better for stationary sources than area or mobile sources.

Receptor Model	Description	Strengths and Weaknesses
TSA [138] TSA requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.[115,139] HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/-ready/hysplit4.html.	**Principle** Similar to CPF, TSA clusters the measured pollutant concentration or calculated source contribution according to the wind pattern. However, air parcel back trajectory, rather than local wind direction, is used. A back trajectory traces the air parcel backward in time from a receptor. The initial height is often between 200 and 1000 m above ground level where the wind direction could differ from the surface wind direction substantively. For each sample i, TSA obtains one or more trajectories and calculates their total residence time in the jth directional sector ($\tau_{i,j}$, i.e., the total number of 1-h trajectory end points that fall into the sector). The pollutant concentration or source contribution in the sample, S_i, is then linearly apportioned into each directional sector according to $\tau_{i,j}$ and averaged over all samples to produce the directional dependent pollutant concentration/source contribution for the period of interest: $$\overline{S_j} = \sum_i S_i \left(\frac{\tau_{ij}}{\sum_i \tau_{ij}} \right) / N$$ **Equation A-18** where N is the number of samples. Compared with CPF and NPR, TSA considers the entire air mass history rather than just the wind direction at the receptor. **Data Needs** TSA requires the time series of pollutant concentration or source contribution at the receptor site, and back trajectories initiated over the site during the sampling duration. Trajectory is usually calculated once every hour so TSA is more suitable for analyzing measurements of >1-h resolution. **Output** TSA reports the avg pollutant concentration or source contribution as a function of wind direction based on back trajectory calculations.	**Strengths** Infer the direction of sources or factors relative to the sampling site. Provide verification for the source identification made by factor analysis method. Account for air mass transport over hundreds to thousands of kilometers and on the order of several days. Can represent plume spread from vertical wind shear at different hours of day by adjusting the initial height of back trajectories. **Weaknesses** Need to generate and analyze the back trajectory data. Uncertainty in back trajectory calculation increases with its length in time. Source contribution depends on not only trajectory residence time but also entrainment efficiency, dispersion, and deposition. Difficult to resolve the direction of more localized sources.

Receptor Model	Description	Strengths and Weaknesses
PSCF [140] PSCF requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.[115,139] HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/-ready/hysplit4.html.	**Principle** Ensemble air parcel trajectory analysis refers to the statistical analysis on a group of trajectories to retrieve useful patterns regarding the spatial distribution of sources. Uncertainties associated with individual trajectory calculations largely cancel out for a sufficient number of trajectories or trajectory segments. As a popular ensemble back trajectory analysis, PSCF estimates the probability that an upwind area contributes to high pollutant concentration or source contribution. Back trajectories are first calculated for each sample at the receptor site. To determine the PSCF, a study domain containing the receptor site is divided into an array of grid cells. Trajectory residence time (the time it spends) in each grid cell is calculated for all back trajectories and for a subset of trajectories corresponding to "high" pollutant concentration or source contribution at the site. PSCF in cell (i,j) is then defined as: $$PSCF_{ij} = \frac{\text{Sum of "high" residence time in cell } (i, j)}{\text{Sum of all residence time in cell } (i, j)}$$ **Equation A-19** The criterion for high pollutant concentration or source contribution is critical for the PSCF calculation. The 75th or 90th percentile of the concentration or factor is often used.[113,141,142] Residence time can be represented by the number of trajectory end points in a cell. **Data Needs** Similar to TSA, PSCF calculation requires the time series of pollutant concentration or source contribution at the receptor site, and back trajectories initiated over the site during the sampling period. Trajectories should be calculated with 1-to 3-h segment to reduce the uncertainty from interpolation (if needed). **Output** PSCF reports the probability that an upwind area contributes to high pollutant concentrations or source contribution at the downwind receptor site. The results are often presented as a contour plot on the map. A high probability usually suggests potential source region.	**Strengths** Infer the location of sources or factors relative to the sampling site. Provide verification for the source identification made by factor analysis method Account for air mass transport over hundreds to thousands of kilometers and on the order of several days. Resolve the spatial distribution of source strength (qualitatively). **Weaknesses** Need to generate and analyze the back trajectory data. Need to correct for the central tendency (residence time always increases toward the receptor site regardless of source contribution). Uncertainty in back trajectory calculation increases with its length in time. Source contribution depends on not only trajectory residence time but also entrainment efficiency, dispersion, and deposition. Difficult to resolve the location of more localized sources.

Receptor Model	Description	Strengths and Weaknesses
SQTBA [117, 143] SQTBA requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.[115,139] HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/-ready/hysplit4.html.	**Principle** SQTBA is another type of ensemble air parcel trajectory analysis. The concept of SQTBA is to estimate the "transport field" for each trajectory ignoring the effects of chemical reactions and deposition. Back trajectories are first calculated for each sample at the receptor site, and a study domain containing the receptor site is divided into an array of grid cells. SQTBA assumes that the transition probability that an air parcel at (x',y',t'), where x' and y' are spatial coordinates and t' means time, will reach a receptor site at (x,y,t) is approximately normally distributed along the trajectory with a standard deviation that increases linearly with time upwind[144,145], thus: $$Q(x, y, t|x', y', z') = \frac{1}{2\pi(at')^2}\exp\left[-\frac{1}{2}\left(\left(\frac{X - x'(t')}{at'}\right)^2 + \left(\frac{Y - y'(t')}{at'}\right)^2\right)\right]$$ **Equation A-20** where (X,Y) is the coordinate of the grid center, a is the dispersion speed, and x'(t') and x' (t') represent the trajectory. The probability field, Q, for a given trajectory is then integrated over the upwind period, τ, to produce a two-dimensional "natural" (nonweighted) transport field: $$T_k(x, y|x', y') = \frac{\int_{-\tau}^{0} Q(x, y, t|x', y', z')}{\int_{-\tau}^{0} dt'}$$ **Equation A-21** After the transport field for each trajectory is established, they are weighted by the corresponding pollutant concentration or source contribution at the receptor site and summed to yield the overall SQTBA field.[117] **Data Needs** SQTBA requires the time series of pollutant concentration or source contribution at the receptor site, and back trajectories initiated over the site during the sampling period. Trajectories should be calculated with 1to 3-h segment to reduce the uncertainty from interpolation (if needed). **Output** SQTBA put more weight on trajectories associated higher pollutant concentration or source contribution and therefore the resulting field may imply the major transport path.	**Strengths** Imply the location of sources or factors relative to the sampling site. Account for air mass transport over hundreds to thousands of kilometers and on the order of several days. Resolve the spatial distribution of source strength (qualitatively). **Weaknesses** Need to generate and analyze the back trajectory data. Need to correct for the central tendency (residence time always increases toward the receptor site regardless of source contribution). Need to estimate dispersion velocity. Involve complicated calculations. Physical meaning of the SQTBA field is unclear. Difficult to resolve the location of more localized sources.

Receptor Model	Description	Strengths and Weaknesses
RTWC [146] RTWC requires the calculation of air parcel back trajectory, which is often accomplished using the HY-SPLIT model.[115,139] HY-SPLIT version 4.5 is available at http://www.arl.noaa.gov/ready/hysplit4.html	**Principle** As an ensemble air parcel trajectory analysis, RTWC requires back trajectories calculated for each sample at the receptor site, and a study domain containing the receptor site divided into an array of grid cells. RTWC assumes that no major pollutant sources are located along "clean" (associated with low pollutant concentrations) trajectories and that "polluted" trajectories picked up emissions along their paths. In practice, RTWC distributes pollutant concentrations at the receptor to upwind grid cells along the back trajectories according to the trajectory residence times in those cells.[117,146] $$S_{i,k} = S_k \frac{\text{resident time in cell } i}{\text{average residence time in each cell}}$$ **Equation A-22** where S_k is the pollutant concentration or source contribution determined upon the arrival of trajectory k and $S_{i,k}$ is the redistributed pollutant concentration or source contribution for cell i upwind. RTWC is known for the problem of "tailing effect," i.e., spurious source areas can be identified when cells are crossed by a very small number of trajectories. Although some corrections were proposed147 these approaches are purely empirical.	**Strengths** Imply the location of sources or factors relative to the sampling site. Account for air mass transport over hundreds to thousands of kilometers and on the order of several days. Resolve the spatial distribution of source strength (qualitatively). **Weaknesses** Need to generate and analyze the back trajectory data. Need to correct for the central tendency and tailing effect. The amount of emission entrainment should not be proportional to the residence time of trajectories (so there is no linear relationship between RTWC field and source strength). Physical meaning of the RTWC field is unclear. Difficult to resolve the location of more localized sources.

A.4. Exposure Assessment

A.4.1. Exposure Assessment Study Findings

Table A-58. Exposure Assessment Study Summaries

Adar et al. (2007, 098635)

Study Design	Cohort
Period	March 2002-June 2002
Location	St. Louis, Missouri
Population	Senior citizens exposed to traffic-related PM
Age Groups	60
Indoor Source	NR
Personal Method	Samples of FeNO were collected between 8:00 and 9:00 a.m. on the mornings before and after each trip. In the hours surrounding these samples, group-level measurements of particle concentrations also were collected using several continuous instruments installed on two portable carts. These carts were first positioned in a central location inside the participants' living facilities 24-h before each trip. The carts remained at the facilities until it was time for the trips, at which point they followed the participants from the health testing room, onto the bus, to the group activity, and to lunch. After the trip home aboard the bus, the carts were returned to the central location in the living facility where they remained until the conclusion of the health testing on the following morning. Continuous measurements of ambient particles and gases also were collected from a central monitoring station in East St. Louis, Illinois. Two portable carts containing continuous air pollution monitors were used to measure group-level micro-environmental exposures to traffic related pollutants, including $PM_{2.5}$, BC, and size-specific particle counts. $PM_{2.5}$ concentrations were measured continuously using a DustTrak aerosol monitor model 8520 with a Nafion diffusion dryer. Integrated samples of $PM_{2.5}$ mass also were collected using a Harvard Impactor for daily calibration of the trip and facility.
Periods	Continuous BC concentrations were measured using a portable aethalometer with a 2.5-µm impaction inlet. Particle counts were measured using a model CI500 optical particle counter with a modified flow rate of 0.1 cubic feet per minute.
Personal Size	NR
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$, PM_{10}
Component(s)	BC, pollen and mold also assessed
Primary Findings	$PM_{2.5}$ exposures resulted in increased levels of FeNO in elderly adults, suggestive of increased airway inflammation. These associations were best assessed by microenvironmental exposure measurements during periods of high personal particle exposures. In pre-trip samples, both microenvironmental and ambient exposures to $PM_{2.5}$ were positively associated with FeNO. For example, an interquartile increase of 4 µg/m^3 in the daily microenvironmental $PM_{2.5}$ concentration was associated with a 13% [95% CI: 2-24) increase in FeNO. After the trips, however, FeNO concentrations were associated predominantly with microenvironmental exposures, with significant associations for concentrations measured throughout the whole day. Associations with exposures during the trip also were strong and statistically significant with a 24% (95% CI: 15-34) increase in FeNO predicted per interquartile increase of 9 µg/m^3 in $PM_{2.5}$. Although pre-trip findings were generally robust and the post-trip findings were generally robust, the post-trip findings were sensitive to several influential days.

Adgate et al. (2002, 030676)

Study Design	Comparison of outdoor, indoor and personal $PM_{2.5}$ in three communities.
Period	April-June, June-August, September-November, 1999
Location	Battle Creek, East St. Paul, and Phillips, Minnesota, constituting the Minneapolis-St. Paul metropolitan area.
Population	Adults in urban areas
Age Groups	Mean age 42 ± 10, range 24-64 yr
Indoor Source	No
Personal Method	Inertial impactors (PEM) in a foam-insulated bag with shoulder strap with the inlet mounted on the front.
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	The relative level of concentrations report in other studies was duplicated. Outdoor < indoor < personal. On days with paired samples (n = 29), outdoor concentrations were significantly lower (mean difference 2.9 µg/m^3, p = 0.026) than outdoor at home.

Adgate et al. (2007, 156196)

Study Design	NR
Period	1999-; April 26-June 20, June 21-August 11, September 23-November 21
Location	Minneapolis-St. Paul metropolitan area
Population	NR
Indoor Source	Cigarette smoke, resuspension of house dust from carpets, furniture and clothes, and emissions from stoves and kerosene heaters (Leaderer et al., 1993; Ferro et al., 2004).
Personal Method	Personal monitoring was conducted for two consecutive days, and was conducted so that the two 24-h averages matched indoor (I) and personal (P) measurements were collected in concert with outdoor (O) samples in each community. Gravimetric concentrations for P and I were collected using inertial impactor environmental monitoring inlets and air sampling pumps. To obtain I measurements, monitors were placed inside each residence in a room where the participants reported spending the most waking hours. P measurements were obtained by carrying personal pumps in small bags. O samples were collected near the approximate geographic center of each neighborhood and monitors ran from midnight to midnight for two consecutive 24-h periods, followed by a day to change filters. Gravimetric O $PM_{2.5}$ concentrations were obtained using a federal reference method sampler.
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	Ag, Al, Ca, Cd, Co, Cr, Cs, Cu, Fe, K, La, Mg, Mn, Na, Ni, Pb, S, Sb, Sc, Ti, Tl, V, Zn
Primary Findings	The relationships among P, I, and O concentrations varied across trace elements (TE). Unadjusted mixed-model results demonstrated that O monitors are more likely to underestimate than overestimate exposure to many of the TEs that are suspected to play a role in the causation of air pollution related health effects. These data also support the conclusion that TE exposures are more likely to be underestimated in a lower income and centrally located community than in a comparatively higher income community. Within the limits of statistical power for this sample size, the adjusted models indicated clear seasonal and community related effects that should be incorporated in long-term exposure estimates for this population.

Adgate et al. (2003, 040341)

Study Design	Time-series epidemiologic study
Period	April-November 1999; spring: 26 April-20 June; summer: 21 June-11 August; fall: 23 September-21 November
Location	Minneapolis-St. Paul, Minnesota
Population	Healthy non-smoking results
Age Groups	24-64 yr (mean age 42 ± 10)
Indoor Source	NR
Personal Method	Personal and indoor gravimetric PM concentrations were collected using $PM_{2.5}$ inertial impactor environmental monitoring inlets and air sampling pumps. Monitors were placed inside each participant's residence in the room where he/she reported spending the majority of their waking hours to obtain I measurements. Participants also carried personal pumps in small bags to obtain P measurements. Start times for indoor and personal monitors were always within a few minutes of each other. Gravimetric O and central site $PM_{2.5}$ concentrations were obtained using a federal reference method sampler and EPA site requirements for ambient sampling. Gravometric samples were collected near the approximate geographic center of each neighborhood, and monitors ran from midnight to midnight for 2 consecutive 24-h periods, followed by a day to change filters.
Personal Size	NR
Microenvironment Size	NR
Ambient Size	NR
Component(s)	NR
Primary Findings	$PM_{2.5}$ concentrations were higher than I concentrations, which were higher than O concentrations. In healthy non-smoking adults, moderate median for correlation between P and I; modest median for correlation between I and O; and minimal median correlation between P and O longitudinal were observed for $PM_{2.5}$ measurements. A sensitivity analysis indicated that correlations did not increase if the days with exposures to environmental tobacco smoke or occupational exposures were excluded. In the sample population neither P nor I monitors provided a highly correlated estimate of exposure to O $PM_{2.5}$ over time. These results suggest that the studies showing relatively strong longitudinal correlation coefficients between P and O $PM_{2.5}$ for individuals sensitive to air pollution health effects do not necessarily predict exposure to $PM_{2.5}$ in the general population.

Allen et al. (2003, 053578)

Study Design	Use of continuous light scattering data to separate indoor PM into indoor- and outdoor-generated components to enhance knowledge of the outdoor contribution to total indoor and personal PM exposures.
Period	November 1999-May 2001
Location	Seattle, WA
Population	Elderly people and children spending most of their time (up to 70%) indoors. The study included healthy elderly subjects, elderly with COPD and coronary heart disease (CHD), and child subjects with asthma.
Age Groups	Age n; 0-29 25; 30-59 36; >60 22; unknown 2
Indoor Source	Suggested (not identified)
Personal Method	NR. Indoor and outdoor sampling conducted
Personal Size	NR
Microenvironment Size	$PM_{2.5}$

Ambient Size	$PM_{2.5}$
Component(s)	S
Primary Findings	A recursive mass balance model can be successfully used to attribute indoor PM to its outdoor and indoor components and to estimate an avg Penetration, air exchange rate, deposition rate, and NH^{4+} for each residence.

Allen et al. (2007, 154226)

Period	Heating seasonOctober-February; Non-heating season March-September
Location	Seattle, WA
Population	NR
Age Groups	NR
Indoor Source	NR
Personal Method	Indoor and outdoor $PM_{2.5}$ was measured using a 10-l/min single-stage Harvard Impactor (HI) with 37-mm Teflon filters. The relationship between particle mass concentration and light scattering coefficient (bsp) was also measured on a continuous basis indoors and outdoors using nephelometers (model 902 and 903).
Personal Size	NR
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	S (measured by XRF)
Primary Findings	The authors showed that RM can reliably estimate F_{inf}. Simulation results suggest that the RM F_{inf} estimates are minimally impacted by measurement error. In addition, the average light scattering response per unit mass concentration was greater indoors than outdoors. Results show that the RM method is unable to provide satisfactory estimates of the individual components of F_{inf}. Individual homes vary in their infiltration efficiencies, thereby contributing to exposure misclassification in epidemiologic studies that assign exposures using ambient monitoring data. This variation across homes indicates the need for home-specific estimation methods, such as RM or S, instead of techniques that give average estimates of infiltration across homes.

Annesi-Maesano et al. (2007, 093180)

Study Design	Population based
Period	March 1999 to October 2000
Location	Bordeaux, France; Clermont-Ferrand, France; Créteil, France; Marseille, France; Strasbourg, France; Reims, France
Population	School children
Age Groups	10.4 ± 0.7 yr
Indoor Source	NR
Personal Method	$PM_{2.5}$ was monitored simultaneously in both schoolyards (proximity level) and fixed-site monitoring stations (city level) using 4L/min battery operated pumps attached to polyethylene filter sampling cartridges.
Personal Size	NR
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	Results show an increased risk for EIB and flexural dermatitis at the period of the survey, past year atopic asthma and SPT positivity to indoor allergens in children exposed to high levels of traffic-related air pollution ($PM_{2.5}$ concentrations exceeding 10 $\mu g/m^3$). Population based findings are also consistent with experimental data that have demonstrated that inhalation of traffic-related air pollutants either individually or in combination, can enhance the immune responses and airway response to inhaled allergens, such as pollens or house dust mites, in atopic subjects.

Balasubramanian and Lee (2007, 156248)

Study Design	Case study of 3 rooms of 1 flat on the 8th floor, and "outside the home."
Period	May 12-23, 2004
Location	Singapore
Population	Residents of an urban area in a densely populated country.
Age Groups	NR
Indoor Source	Time-activity logs identified tobacco smoking, cooking, household cleaning and general resident movements.
Personal Method	NR
Personal Size	NR
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Primary Findings	I/O suggest that chemicals such as Cl^-, Na^+, Al, Co, Cu, Fe, Mn, Ti, V, Zn, and EC were derived from the migration of outdoor particles (I/O <1 or ~1).

Barn et al. (2008, 156252)

Study Design	Measure indoor F_{inf} of $PM_{2.5}$ from forest fires/wood smoke, effectiveness of high-efficiency particulate air (HEPA) filter air cleaners in reducing indoor $PM_{2.5}$, and to analyze the home determinants of F_{inf} and air cleaner effectiveness (ACE).
Period	2004-2005 (summer 2004 and 2005, winter 2004)
Location	British Columbia, Canada
Population	Homes affected by either forest fire smoke or residential wood smoke
Age Groups	NR
Indoor Source	NR
Personal Method	Personal Data RAM for ambient air sampling
Personal Size	Indoor home $PM_{2.5}$
Microenvironment Size	NR
Ambient Size	Outdoor home $PM_{2.5}$
Component(s)	NR
Primary Findings	Use of HEPA filter air cleaners can dramatically reduce indoor $PM_{2.5}$ concentrations. Number of windows and season predict F_{inf} ($p< 0.001$).

Baxter et al. (2007, 092726)

Study Design	Part of a prospective birth cohort study performed by the Asthma Coalition for Community, Environment, and Social Stress (ACCESS)
Period	2003-2005. Non-heating season: May to October; Heating season: December to March
Location	Boston (urban)
Population	Lower socio-economic status (SES) households
Age Groups	NR
Indoor Source	NR
Personal Method	$PM_{2.5}$ samples were collected with Harvard personal environmental monitors (PEM). NO concentrations were measured using Yanagisawa passive filter badges.
Personal Size	NR
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	EC
Primary Findings	The authors' regression models indicated that $PM_{2.5}$ was influenced less by local traffic but had significant indoor sources, while EC was associated with local traffic and NO_2 was associated with both traffic and indoor sources. However, local traffic was found to be a larger contributor to indoor NO_2 where traffic density is high and windows are opened, whereas indoor sources are a larger contributor when traffic density is low or windows are closed. Similarly, traffic contributed up to 0.2 $\mu g/m^3$ to indoor EC for homes with open windows, with an insignificant contribution for homes where windows were closed.; Comparing models based on p-values and using a Bayesian approach yielded similar results, with traffic density volume within a 50 m buffer of a home and distance from a designated truck route as important contributors to indoor levels of NO_2 and EC, respectively. However, results from the Bayesian approach also suggested a high degree of uncertainty in selecting the best model. The authors concluded that by utilizing public databases and focused questionnaire data they could identify important predictors of indoor concentrations for multiple air pollutants in a high-risk population.

Baxter et al. (2007, 092725)

Study Design	Simultaneous indoor and outdoor samples taken in 43 low SES homes in heating and non-heating seasons. Homes were selected from a prospective birth cohort study of asthma etiology (n = 25). Non-cohort homes were in similar neighborhoods (n = 18).
Period	2003-2005
Location	Boston, Massachusetts
Population	Lower SES populations in urban areas
Indoor Source	Home type, year built, tobacco smoke, opening windows, time spent cooking, use of candles or air freshener, cleaning activities, air conditioner use.
Personal Method	NR
Personal Size	NR
Microenvironment Size	$PM_{2.5}$
Ambient Size	NR
Component(s)	EC (m-1 x 10^{-5}); Ca (ng/m^3); Fe (ng/m^3); K (ng/m^3); Si (ng/m^3); Na (ng/m^3); Cl (ng/m^3); Zn (ng/m^3); S (ng/m^3); V (ng/m^3)
Copollutant(s)	NO_2
Primary Findings	The effect of indoor sources may be more pronounced in high-density multi-unit dwellings. Cooking times, gas stoves, occupant density and humidifiers contributed to indoor pollutants.

BéruBé et al. (2004, 007894)

Study Design	6 homes in Wales and Cornwall were monitored four times per year, inside samples in the living areas and outside the home.
Period	NR but < 2003
Location	Wales and Cornwall, UK
Population	Urban, suburban, and rural homes
Indoor Source	ETS, pets, cleaning, traffic load
Personal Method	NR
Personal Size	NR
Microenvironment Size	PM_{10}
Ambient Size	NR
Component(s)	NR
Primary Findings	There are greater masses of PM_{10} indoors, and that the composition of the indoor PM_{10} is controlled by outdoor sources and to a lesser extent by indoor anthropogenic activities, except in the presence of tobacco smokers. The indoor and outdoor PM_{10} collected was characterized as being a heterogeneous mixture of particles (soot, fibers, sea salt, smelter, gypsum, pollen and fungal spores).

Branis et al. (2005, 156290)

Study Design	Human exposure assessment in a university lecture hall
Period	Oct. 8, 2001-Nov. 11, 2001
Location	Prague, Czech Republic
Population	University students
Age Groups	NR
Indoor Source	Presence of people identified as a source of coarse particles; outdoor air identified as a source of indoor fine particles ($PM_{1.0}$ and $PM_{2.5}$)
Personal Method	Harvard impactors (HI) with membrane Teflon filters
Personal Size	PM_1, $PM_{2.5}$, PM_{10}
Microenvironment Size	PM_1, $PM_{2.5}$, PM_{10}
Ambient Size	PM_{10}
Component(s)	NR
Primary Findings	Presence of people is an important source of coarse particles indoors; Outdoor air may be an important source of fine indoor particles.

Brunekreef et al. (2005, 090486)

Study Design	Exposure assessment
Period	Winter and spring 1998-1999
Location	Amsterdam and Helsinki
Population	Elderly
Age Groups	50-84 yr
Indoor Source	NR
Personal Method	Amsterdam Gillian with made to fit bags with belt with GK2.05 cyclone samplers 4L/min; Helsinki BGI with shoulder strap or backpack with GK2.05 cyclone samplers 4 L/min.
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	SO_4^{2-}
Primary Findings	In both cities, personal and indoor $PM_{2.5}$ were highly correlated with outdoor concentrations.

Chillrud et al. (2004, 054799)

Study Design	Repeated measures on a cohort of high school students in New York City
Period	Summer and winter of 1999 (eight weeks each)
Location	Manhattan, Bronx, Queens, Brooklyn, NY
Population	Persons traveling the subway
Age Groups	14-18 yr
Indoor Source	No
Personal Method	Sampling packs carried by subjects
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$ (home indoor and home outdoor)
Ambient Size	$PM_{2.5}$. Urban fixed-site and upwind fixed site operated for three consecutive 48-h periods each week.
Component(s)	Elemental Fe, Mn, and Cr are reported in this study out of 28 elements sampled.
Primary Findings	Personal samples had significantly higher concentration of Fe, Mn, and Cr than home indoor and ambient samples. The ratios of Fe (ng/µg of $PM_{2.5}$) vs Mn (pg/µg $PM_{2.5}$) showed personal samples to be twice the ratio for crustal material. Similarly for the Cr/Mn ratio. The ratios and strong correlations between pairs of elements suggested steel dust as the source. Time-activity data suggested subways as a source of the elevated personal metal levels.

Conner and Williams (2004, 156364)

Study Design	This is part of the EPA Baltimore PM Study of the Elderly.
Period	July-August, 1998
Location	Towson, Maryland
Population	65+ adults
Age Groups	65+ yr
Indoor Source	Personal sampling devices (PEM)
Personal Method	$PM_{2.5}$
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	NR
Primary Finding(s)	A greater variety of particles was observed in the personal samples compared to the fixed-location apartment samples.

Cortez-Lugo et al. (2008, 156368)

Study Design	Cohort
Period	Feb-Nov 2000
Location	Mexico City, Mexico
Population	Ambulatory adults with moderate to severe COPD, active smokers excluded
Age Groups	Adults
Indoor Source	carpeting, aerosol sprays used, boiler use and location, animals, mold, tobacco smoking, windows closed
Personal Method	Personal pumps with 37-mm Teflon filters, flow rate 4 l/min in a bag with shoulder strap. The impactor was near the breathing zone
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$, PM_{10}
Ambient Size	$PM_{2.5}$, PM_{10}
Component(s)	NR
Primary Findings	Indoor $PM_{2.5}$ concentrations explained 40% of the variability of personal exposure. The best predictors of personal exposure were indoor contact with animals (12%), mold (27%), being present during cooking (27%), and aerosol use (17%).

Crist et al. (2008, 156372)

Study Design	Indoor, outdoor, and personal monitoring
Period	January 1999-August 2000
Location	Ohio
Population	Fourth & fifth-grade children
Age Groups	9-11 yr old
Indoor Source	Filter, portable pump
Personal Method	Filter, $PM_{2.5}$
Personal Size	Indoor school; Filter, $PM_{2.5}$
Microenvironment Size	Outdoor school; Filter, $PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	Higher correlation was observed between P and I compared with the correlation between either P and ambient (A) or I and A.

Delfino et al. (2004, 056897)

Study Design	Panel study with repeated measures
Period	Sep-Oct 1999 or Apr-Jun 2000
Location	Alpine, California
Population	Children
Age Groups	9-17 yr
Indoor Source	No
Personal Method	Personal dataRAM (pDR) carried at waist level using a fanny pack, shoulder harness, or vest.
Personal Size	0.1-10 μm
Microenvironment Size	PM_{10} and $PM_{2.5}$; measured immediately outside the house and in the living room of the home.
Ambient Size	PM_{10}
Copollutant(s)	O_3 and NO_2 measured at central site
Primary Findings	Percent predicted FEV_1 was inversely associated with personal exposure to fine particles. Also with indoor, outdoor and central site gravimetric $PM_{2.5}$, PM_{10}, and with hourly TEOM PM_{10}.

Delfino et al. (2006, 090745)

Study Design	Cohort. Measured daily expired NO (FeNO)
Period	Aug-Dec 2003
Location	Riverside and Whittier, California
Population	Children with asthma exacerbations in previous 12 months, non-smokers, non-smoking households
Age Groups	9-18 yr
Indoor Source	No
Personal Method	Wore a backpack during waking hours for $PM_{2.5}$, EC and OC, NO_2, temperature, and relative humidity. Exhaled air collected in Mylar bags to analyze for NO.
Personal Size	24-h $PM_{2.5}$; 1-h max $PM_{2.5}$; 8-h max $PM_{2.5}$; 24-h NO_2
Microenvironment Size	NR
Ambient Size	24-h $PM_{2.5}$; 24-h PM_{10}; 8-h max O_3; 8-h max NO_2; 24-h NO_2; 8-h max CO
Component(s)	24-h $PM_{2.5}$ EC; 24-h $PM_{2.5}$ OC
Primary Findings	The strongest positive associations were between FeNO and 2-day average pollutant concentrations. Per IQR increases 1.1 ppb FeNO/24 μg/m^3 personal $PM_{2.5}$.; 0.7 ppb FeNO/0.6 μg/m^3 personal EC; 1.6 ppb FeNO / 17 ppb personal NO_2 Ambient $PM_{2.5}$ and personal and ambient EC were significant only when subjects were taking inhaled corticosteroids. Subjects taking both inhaled steroids and antileukotrienes had no significant associations. Distributed lag models showed personal $PM_{2.5}$ in the preceding 5 h was associated with FeNO.

Diapouli et al. (2007, 156397)

Study Design	Exposure assessment. Sampling of schools, residence, private vehicle
Period	Schools- 11/2003-02/2004 and 10/2004-12/2004.; Residence- 10/2004; Vehicle- 10/204-12/2004
Location	Athens, Greece
Population	Primary school children
Age Groups	NR
Indoor Source	NR
Personal Method	Handheld portable Condensation Particle Counters (TSI, Model 3007) were used for all sampling locations. Primary schools indoor measurements were primarily conducted inside classrooms, at table height. However, at three of the schools, rooms of different uses were selected. These included a teachers' office (where smoking was permitted), a computer day lab (used by students only part of the day), and a library and gymnasium (where intense activity took place almost all day long). Outdoor measurements took place in the yard of each school. Residence samples were taken in a bedroom at breathing height and on the terrace, for indoor and outdoor samples, respectively. In-vehicle samples were taken by placing the CPC 3700 on the passenger seat while the vehicle drove along predetermined routes.
Personal Size	NR
Microenvironment Size	0.01-1 μm
Ambient Size	0.01-1 μm
Component(s)	NR
Primary Findings	The results showed that children attending primary schools in the Athens area are exposed to significant PM concentration levels, both indoors and outdoors. Vehicular emissions seem to be a major contributor to the measured outdoor concentration levels at the studied sites. Indoor PM concentrations appeared to be influenced by both vehicular emissions and indoor sources including cleaning activities, smoking, a high number of people in relation to room volume and furniture material (i.e., carpet). UFPs concentrations diurnal variation, both outside the schools and the residence, supports the close relation of UFPs levels with traffic density. Indoor concentrations within schools exhibited variability during the school day only when there were significant changes in room occupancy. 24-h variation of indoor concentrations at the residence were well correlated with the outdoor concentration (R^2 = 0.89).

Diapouli et al. (2008, 190893)

Study Design	Indoor, outdoor air monitoring of PM. To determine children exposure in school environment. To evaluate relationship between indoor and outdoor levels.
Period	Athens, Greece
Location	Primary schools
Population	NR
Indoor Source	Indoor PM_1, $PM_{2.5}$, PM_{10}, presence of children and activities of children in classrooms, infiltrated vehicular exhaust
Personal Method	Harvard PEM, Teflon filters Dust Trak Condensation particle counter
Personal Size	NR
Microenvironment Size	PM_1, $PM_{2.5}$, PM_{10}
Ambient Size	PM_1, $PM_{2.5}$, PM_{10}
Component(s)	NO_3^-, SO_4^{2-}
Primary Findings	High levels of PM_{10} and $PM_{2.5}$ measured indoors and outdoors. PM_{10} more variable spatially than $PM_{2.5}$. I/O ratio for PM_{10} and $PM_{2.5}$ close to 1 at almost all sites. Ratio of PM_1 smaller than 1 in all cases. Vehicular traffic presumed to be the main source of PM_1. Indoor $PM_{2.5}$ and PM_{10} levels dependent on the amount of activity in classroom and outdoor levels. Indoor SO_4^{2-} concentrations strongly associated with outdoor levels. Result suggests that SO_4^{2-} can be used as a proper surrogate for indoor PM of outdoor origin.

Ebelt et al. (2005, 056907)

Study Design	Personal exposure assessment related to health outcomes for a sensitive sub-population
Period	Summer 1998
Location	Vancouver, British Columbia, Canada
Population	16 persons who had COPD
Age Groups	Mean subject age 74 yr, Range 54 to 86
Indoor Source	Separated total personal exposure into “ambient” and “non-ambient” based on sulfate results and modeling.
Personal Method	24-h integrated filter sample
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$, PM_{10}, $PM_{10-2.5}$
Ambient Size	$PM_{2.5}$, PM_{10}, $PM_{10-2.5}$
Component(s)	SO_4^{2-}
Primary Findings	Ambient exposures and (to a lesser extent) ambient concentrations were associated with health outcomes. Total and nonambient particle exposures were not.

Farmer et al. (2003, 089017)

Study Design	Case control molecular epidemiology studies of carcinogenic environmental pollutants, particularly PAHs
Period	12 months
Location	Prague, Czech Republic (2 sites); Košice, Slovak republic; Sofia, Bulgaria
Population	Policeman and busdrivers usually working through busy streets in 8-10 h shifts and a control population.
Age Groups	Variable, range not stated
Indoor Source	NR
Personal Method	Personal Monitoring Devices; Blood and Urine Samples; Stationary Versatile Air Pollution Samplers (VAPS)
Personal Size	PM_{10}
Microenvironment Size	NR
Ambient Size	PM_{10}; $PM_{2.5}$ (not reported)
Component(s)	Extractable organic matter (EOM), B[a]P, c-PAHs
Primary Findings	EOM per PM_{10} was at least 2-fold higher in winter than in summer, and c-PAHs over 10-fold higher in winter than in summer. Personal exposure to B[a]P and to total c-PAHs in Prague ca. was 2-fold higher in the exposed group compared to the control group, in Košice ca. 3-fold higher, and in Sofia ca. 2.5-fold higher.

Ferro et al. (2004, 055387)

Study Design	Case study, 1 home
Period	Redwood City, California
Location	NR
Population	NR
Age Groups	NR
Personal Method	Co-located real-time particle counters and integrated filter samplers (Met-One Model 237B) were used to measure personal (PEM), indoor (SIM) and outdoor (SAM) PM concentrations. The PEM was attached to a backpack frame and worn by the investigator while performing prescribed activities. The SIM was attached to a six foot step-ladder with the intake at breathing height. The SAM was located under a two-sided roofed shed in the backyard of the home with the filter samplers supported by a metal stand and the real-time particle counters sitting on a table.
Personal Size	PM_5
Microenvironment Size	$PM_{2.5}$; PM_5
Ambient Size	$PM_{2.5}$; PM_5
Component(s)	NR
Primary Findings	The results of this study indicate that house dust resuspended from a range of human activities increases personal PM concentrations and this resuspension effect significantly contributes to the personal cloud. The results of this study also suggest that normal human activities that resuspend house dust may contribute significantly to the strong correlations found between personal exposure and indoor PM concentrations in previous studies. The PEM/SIM ratios for human activity presented in this paper are also in the range of those reported by previous studies.

Gadkari and Pervez (2007, 156459)

Study Design	Evaluation of relative source contribution estimates of various routes of personal RPM in different urban residential environments.
Period	Summer 2004 (March 15-June 15)
Location	Chattisgarh, India
Population	All likely. Not specified
Age Groups	21-61 yr, average age 40 ± 15 yr
Indoor Source	No
Personal Method	Personal respirable dust samplers (RDS) with GFF
Personal Size	RPM
Microenvironment Size	NR
Ambient Size	RPM
Component(s)	Fe, Ca, Mg, Na K, Cd, Hg, Ni, Cr, Zn, As, Pb, Mn and Li
Primary Findings	Authors concluded that "(1) indoor activities and poor ventilation qualities are responsible for major portion of high level of indoor RPM, (2) majority of personal RPM is greatly correlated with residential indoor RPM, (3) time–activity diary of individuals has much impact on relationship investigations of their personal RPM with their respective indoor and ambient-outdoor RPM levels; as reported in earlier reports and (4) residential indoors, local road-traffic and soil-borne RPMs are the dominating routes of personal exposure compared to ambient outdoor RPM levels."

Gauvin et al. (2002, 034893)

Study Design	Fine particle exposure assessment for children in French urban environments, part of VESTA study
Period	March 1998-December 2000
Location	Paris, Grenoble, Toulouse, France
Population	Children aged 8-14 yr
Indoor Source	ETS from mother, rodents at home.
Personal Method	SKC pump 4 Lpm with $PM_{2.5}$ inlet and 37 mm, 2 micron Teflon filter
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	PM_{10}
Component(s)	NR
Primary Findings	The final model explains 36% of the between subjects variance in $PM_{2.5}$ exposure, with ETS contributing more than a third to this.

Graney et al. (2004, 053756)

Study Design	The study was designed to assess the trace metal quantification abilities of several analytical methods to measure the total as well as soluble amounts of metals with $PM_{2.5}$ collected from indoor and PM samples. (X-ray fluorescence and instrumental neutron activation analysis)
Location	Retirement facility in Towson, Maryland
Population	Retirement facility with subjects who spent 94% of their time indoors
Age Groups	Mean age = 84 yr
Indoor Source	NR
Personal Method	Measured using personal exposure monitors (MSP Inc) with nozzle to remove particles > 4 µm
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	NR
Component(s)	42 elements were analyzed for in the $PM_{2.5}$ samples collected from personal and well as indoor samples
Primary Findings	Most of the extractable components of the metals were in a water-soluble form suggesting a high potential for bioavailability of elements from respiratory exposure to $PM_{2.5}$. Based on comparison of trace metals in central I site vs. P samples, resident activities result in exposure to higher concentration of soluble trace metals.

Haverinen-Shaughnessy et al. (2007, 156526)

Study Design	Cross-sectional
Period	Winter, year not reported
Location	Eastern Sweden
Population	Elementary school teachers
Age Groups	NR
Personal Method	Button inhalable aerosol samplers
Personal Size	Particle mass
Microenvironment Size	Particle mass
Ambient Size	NR
Component(s)	Absorbance coefficient/m x 10^{-5}; Total fungi (spores/m^3); Total bacteria (cells/m^3); Viable fungi MEA (CFU/m^3); Viable fungi DG18 (CFU/m^3); Viable bacteria (CFU/m^3)
Primary Findings	The recall period of 7 days provided the most reliable data for health effect assessment. Both personal exposure and concentrations of pollutants at home were more frequently associated with health symptoms than work exposures.

Ho et al. (2004, 056804)

Study Design	Human exposure assessment
Period	25 Sept. 2002 to 8 March 2003
Location	Hong Kong
Population	Occupied buildings located near major roadways
Age Groups	NR
Indoor Source	Yes. Regression of indoor versus outdoor concentrations of OC and EC revealed an indoor source of OC not present for EC, presumably due to such activities of cooking, smoking, and cleaning.
Personal Method	Co-located mini-volume samplers (flow rate 5 L/min) and Partisol model 2000 sampler with 2.5 μm inlet. All samples on 47 mm Whatman quartz microfiber filters, weighed on an electronic microbalance. Analyzed for OC and EC using DRI Model 2001 Thermal/Optical Carbon Analyzer.
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	OC, EC, OM, TC
Primary Findings	The major source of indoor EC, OC, and $PM_{2.5}$ appears to be penetration of outdoor air, with a much greater attenuation in mechanically ventilated buildings.

Hoek et al. (2008, 156554)

Study Design	Exposure assessment, characterizing indoor/outdoor particle relationships
Period	October 2002-March 2004
Location	4 European cities Amsterdam, Athens, Birmingham, Helsinki
Population	Urban populations
Age Groups	NR
Indoor Source	Smoking, candle burning, cooking/frying
Personal Method	No personal exposure assessment was conducted
Personal Size	NR
Microenvironment Size	PM_{10}, $PM_{2.5}$, $PM_{10-2.5}$, Ultrafine (UFP)
Ambient Size	PM_{10}, $PM_{2.5}$, $PM_{10-2.5}$, UFP
Component(s)	soot, sulfate
Primary Findings	Correlation between 24-h average central site and indoor concentrations was lower for UFP than for $PM_{2.5}$, soot, or SO_4^{2-}, probably related to greater losses during infiltration due to smaller particle size. Infiltration factors for UFP and $PM_{2.5}$ were low.

Hopke et al. (2003, 095544)

Study Design	Exposure assessment
Period	26 July to 22 August 1998
Location	Retirement facility in Towson, MD
Population	Elderly residents
Age Groups	Mean age of 84
Indoor Source	Ammonium sulfate and ammonium nitrate, secondary sulfate, OC, and motor vehicle exhaust
Personal Method	Inertial impactor PEM in the breathing zone of the subjects
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	SO_4^{2-}
Primary Findings	Personal exposures were influenced by a combination of indoor and outdoor factors. Indoor factors included gypsum, personal grooming products, and an unknown indoor source. Outdoor factor included SO_4^{2-}, soil, and an unknown factor. Outdoor factors accounted for 63% of personal exposure, and SO42- was the largest ambient contributor to personal exposure (48%).

Jacquemin et al. (2007, 156600)

Study Design	Assessment of relationship between outdoor and personal concentrations of $PM_{2.5}$ absorbance and sulfur among post-myocardial infarction patients
Period	January 2004-June 2004
Location	Barcelona, Spain
Population	Survivors of a myocardial infarction exposed to ETS
Age Groups	n = 38, including 32 and 15 over age 64.
Indoor Source	ETS
Personal Method	Personal samplers (BGI GK2.05 cyclones and battery operated BGI AFC400S pumps)
Personal Size	$PM_{2.5}$
Microenvironment Size	NA
Ambient Size	$PM_{2.5}$
Component(s)	S
Primary Findings	Ambient measurements of light extinction and S can be used as surrogates to personal $PM_{2.5}$ exposure, especially for those exposed to ETS.

Janssen et al. (2005, 088692)

Study Design	Panel Study
Period	Amsterdam 11/2/1998-6/18/1999; Helsinki 11/1/1998-4/30/1999
Location	Amsterdam, The Netherlands; Helsinki, Finland
Population	Elderly Cardiovascular Patients
Age Groups	50-84 yr
Indoor Source	No
Personal Method	Personal $PM_{2.5}$ GK2.05; cyclones; indoor & outdoor Harvard Impactors; Reflectance EEL 43 reflectometers; Elemental Composition Tracor Spectrace 5000 ED-XRF system
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	Estimated EC, elemental composition of a subset of personal, indoor and outdoor samples
Primary Findings	For most elements, personal and indoor; concentrations were lower than and highly correlated with outdoor concentrations. The highest correlations (median r = 0.9) were found for sulfur and particle absorbance (EC), which both represent fine; mode particles from outdoor origin. Low correlations were observed for elements that represent the coarser part of the $PM_{2.5}$ particles (Ca, Cu, Si, Cl^-).

Jedrychowski et al. (2006, 156606)

Study Design	Prospective cohort
Period	11/2000-3/2003
Location	Krakow, Poland
Population	Non-smoking pregnant women
Age Groups	Yes
Personal Method	Personal Exposure Monitor Sampler (PEMS, Harvard; School of Public Health)
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	PM_{10}
Component(s)	NR
Primary Findings	The contribution of the background ambient PM_{10} level was a very strong determinant of the total personal exposure to $PM_{2.5}$, and it explained about 31% of variance between the subjects.

Johannesson et al. (2007, 156614)

Study Design	Cohort
Period	Spring and fall seasons of 2002 and 2003
Location	Gothenburg, Sweden
Population	General adult population
Age Groups	23-51 yr
Indoor Source	NR
Personal Method	Fine particles were measured for 24 h using both personal and stationary monitoring equipment. Personal monitoring of $_{PM2.5}$ and PM_1 was carried out simultaneously with parallel measurements of $PM_{2.5}$ and PM_1 indoors in living rooms and outside the house on a balcony, porch, etc. In addition, urban background $PM_{2.5}$ levels were measured. Personal monitoring was performed in two ways. The 20 randomly selected subjects carried personal monitoring equipment for $PM_{2.5}$ only, while the 10 staff members carried two pieces of personal monitoring equipment at the same time. On the first measuring occasion, the staff members carried one $PM_{2.5}$ cyclone and one PM_1 cyclone. On the second occasion, duplicate monitors for $PM_{2.5}$ were used. For personal and residential monitoring, the BGI Personal Sampling Pump was used together with the GK2.05 cyclone for $PM_{2.5}$ sampling and the Triplex cyclone SCC1.062 for PM_1sampling. The personal sampling pump was placed in a small

	shoulder bag and the cyclone attached to the shoulder strap near the subject's breathing zone. The personal monitoring equipment was carried by the subject during awake time. During the night, it was placed in the living room. For indoor monitoring in living rooms, cyclones ($PM_{2.5}$ and PM_1) were placed at about 1.5 m above the floor. The same setup was used for residential outdoor monitoring. The urban background monitor was placed on top of a roof somewhat south of the city center but not near any major highway.
Personal Size	$PM_{2.5}$; PM_1
Microenvironment Size	$PM_{2.5}$; PM_1
Ambient Size	$PM_{2.5}$; PM_1
Component(s)	BS
Primary Findings	Personal exposure of $PM_{2.5}$ correlated well with indoor levels, and the associations with residential outdoor and urban background concentrations were also acceptable. Statistically significantly higher personal exposure compared with residential outdoor levels of $PM_{2.5}$ was found for nonsmokers. PM_1 made up a considerable proportion (about 70–80%) of $PM_{2.5}$. For BS, significantly higher levels were found outdoors compared with indoors, and levels were higher outdoors during the fall than during spring. There were relatively low correlations between particle mass and BS. The urban background station provided a good estimate of the residential outdoor concentrations of both $PM_{2.5}$ and BS2.5 within the city. The air mass origin affected the outdoor levels of both $PM_{2.5}$ and BS2.5; however, no effect was seen on personal exposure or indoor levels.

Kaur et al. (2005, 086504)

Study Design	Exposure assessment, evaluation of exposures between modes of transport, routes, timing
Period	April 28-May 23, 2003
Location	Street canyon intersection in Central London, UK
Population	Users of an urban street canyon intersection
Age Groups	NR
Indoor Source	NR
Personal Method	$PM_{2.5}$ measured usnig high-flow gravimetric personal samplers ($PM_{2.5}$) operating at a flow rate of 16 l/min carried in a backpack with sampling head positioned in personal breathing zone. UFP measured using TSI P-TRAK particle counters in which isopropyl alcohol condenses to form droplets that can be easily counted by a photodetector as they pass through a laser beam.
Personal Size	$PM_{2.5}$, UFP (0.02-1.0um)
Microenvironment Size	$PM_{2.5}$, UFP (0.02-1.0um)
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	Personal exposures to $PM_{2.5}$ while walking were significantly lower then while riding in a car or taxi, likely a function of greater distance to roadside. No significant differences in $PM_{2.5}$ were observed between exposures on the high traffic road compared with the backroad. Personal exposure levels were lowest during midday measurements for $PM_{2.5}$ and highest in the early evening. Personal exposures to ultrafine particles were lowest while walking and highest while riding the bus. Exposures to ultrafine particles were also significantly higher on the high traffic road and during morning measurements. Exposure to ultrafine particles were highest in the morning, likely the result of peak traffic density in the morning. Exposure assessment also revealed that the background and curbside monitoring stations were not representative of the personal exposure of individuals to $PM_{2.5}$ and CO at and around a street canyon intersection.

Kaur et al. (2005, 088175)

Study Design	Personal exposure assessment of pedestrians walking along high-traffic urban road
Period	April 19, 2004-June 11, 2004
Location	Central London, UK
Population	Pedestrians
Age Groups	NR
Indoor Source	NR
Personal Method	$PM_{2.5}$ gravimetric filter measurement, UFP (0.02-1 µm) P-TRAK device, reflectance reflectometer measurement of $PM_{2.5}$ filter
Personal Size	$PM_{2.5}$, UFP (0.02-1 µm)
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$, UFP (0.02-1 µm)
Component(s)	Absorbance of $PM_{2.5}$ filter
Primary Findings	$PM_{2.5}$ pedestrian exposure was well correlated with and above background fixed-site monitoring levels. PM pedestrian exposure was influenced by proximity to curbside and the side of the road walked on.

Kim et al. (2005, 156640)

Study Design	Panel study
Period	8/1999-11/2001
Location	Toronto, Canada
Population	Cardiac-compromised patients
Age Groups	Mean age 64 yr
Indoor Source	Gas range (68%); indoor grill (11%); outdoor barbeque (30%); Gas heating fuel (68%); Oil heating fuel (7%)
Personal Method	Rupprecht and Patashnick ChemPass Personal Sampling System
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	Personal $PM_{2.5}$ exposures were higher than outdoor ambient levels. Personal $PM_{2.5}$ exposures levels were correlated with ambient levels, mean r = 0.58

Koistinen et al. (2004, 156655)

Study Design	Representative Population-based study
Period	Oct 1996-Dec 1997
Location	Helsinki, Finland
Population	Non-smoking adults not exposed to environmental tobacco smoke.
Age Groups	Adults 25-55 yr
Indoor Source	Soil from outdoors, cooking, smoking, aerosol cleaners, sea salt, combustion sources
Personal Method	Integrated 24-h filter sample
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	BS
Primary Findings	Population exposure assessment of $PM_{2.5}$, based on outdoor fixed-site monitoring, overestimates exposures to outdoor sources like traffic and long-range transport and does not account for the contribution of significant indoor sources.

Kousa et al. (2001, 025270)

Study Design	Population based exposure assessment
Period	October 1996 to June 1998
Location	Helsinki, Finland; Basel, Switzerland; Prague, Czech Republic; Athens, Greece
Population	Adult urban populations
Age Groups	25-55 yr
Indoor Source	Sometimes ETS
Personal Method	Integrated 48-h filter sample
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$, PM_{10}
Component(s)	NR
Primary Findings	Throughout the study, the highest correlations were those between personal exposures and indoor concentrations, which suggests that indoor sources were important. Correlations were generally lower between ambient concentrations and personal exposures.

Koutrakis et al. (2005, 095800)

Study Design	Panel study
Period	Baltimore 6/28/98-8/22/98 (summer), 2/1/99-3/16/99 (winter); Boston 6/13/99-7/23/99 (summer), 2/1/00-3/12/00 (winter)
Location	Baltimore, MD Boston, MA
Population	Healthy older adults, children, adults with COPD
Age Groups	Children 9-13 y/o; Seniors 65+ y/o
Indoor Source	NR
Personal Method	Personal exposure samples of $PM_{2.5}$; were collected using a specially designed multipollutant sampler (Demokritou et al. 2001). $PM_{2.5}$ was collected using personal environmental monitors (PEMs) and 37-mm; Teflon filters (Teflo, Gelman Sciences, Ann Arbor MI).
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	EC, SO_4^{2-}
Primary Findings	Ambient $PM_{2.5}$ and SO_4^{2-} are strong predictors of respective personal exposures. Ambient SO_4^{2-} is a strong predictor of personal exposure to $PM_{2.5}$. Because $PM_{2.5}$ has substantial indoor sources and SO_4^{2-} does not, the investigators; concluded that personal exposure to SO_4^{2-} accurately reflects exposure to ambient $PM_{2.5}$ and therefore the ambient component of personal exposure to $PM_{2.5}$ as well.

Lai et al. (2004, 056811)

Study Design	Personal exposure study
Period	December 1998-February 2000
Location	Oxford, UK
Population	Adults
Age Groups	25-55 yr (avg = 41)
Indoor Source	Cooking, active smoking, passive smoking heating by gas heater
Personal Method	Integrated 48-h filter samples
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	Ag, Cr, Mn, Si, Al, Cu, Na, Sm, As, Fe, Ni, Sn, Ba, Ga, P, Sr, Br, Ge, Pb, Ti, Ca, Hg, Rb, Tl, Cd, I, S, Tm, Cl, K, Sb, V, Co, Mg, Se, Zn, Zr
Primary Findings	Personal exposures were influenced by both indoor and ambient sources, and indoor levels exceeded ambient levels for $PM_{2.5}$ as well as for VOCs and eight other compounds. Correlation between personal and indoor $PM_{2.5}$ was 0.60 ($p < 0.001$).

Larson et al. (2004, 098145)

Study Design	Time-series epidemiologic study
Period	Sep 26, 2000-May 25, 2001
Location	Seattle, Washington
Population	"Susceptible Populations"
Age Groups	Time-activity diary
Personal Method	Harvard Personal Environmental Monitor
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$ outside subject's residence, and inside residence
Ambient Size	$PM_{2.5}$ at Central outdoor site (downtown Seattle)
Component(s)	Light absorbing carbon (LAC) and trace elements
Primary Findings	Five sources of $PM_{2.5}$ identified vegetative burning, mobile emissions, secondary sulfate, a source rich in chlorine, and crustal-derived material. The burning of vegetation (in homes) contributed more $PM_{2.5}$ mass on average than any other sources in all microenvironments.

Li et al. (2003, 047845)

Study Design	Concurrent 10-min avg indoor and outdoor concentrations of PM_{10} and $PM_{2.5}$ were recorded for 2 days each in 10 homes with swamp coolers
Period	Summer 2001
Location	El Paso, Texas
Population	Cooking, cleaning, walking
Age Groups	NR
Indoor Source	NR
Personal Method	$PM_{2.5}$ and PM_{10}; indoor and outdoor; tapered element oscillating microbalance (TEOM) instruments. 2 days were monitored for $PM_{2.5}$, and 2 for PM_{10}.
Personal Size	NR
Microenvironment Size	NR
Primary Findings	Evaporative coolers were found to act as PM filters, creating indoor concentrations approximately 40% of outdoor PM_{10} and 35% of outdoor $PM_{2.5}$, regardless of cooler type.

Liu et al. (2003, 073841)

Study Design	Comprehensive exposure assessment
Period	1999-2001
Location	Seattle, WA
Population	High-risk sub populations
Age Groups	Children 6-13 yr, elderly 65-90 yr (one person was below 65, but his/her age was not specified)
Personal Method	Harvard Personal Environmental Monitor for $PM_{2.5}$ ($HPEM_{2.5}$)
Personal Size	$PM_{2.5}$, PM_{10}
Microenvironment Size	$PM_{2.5}$, PM_{10}
Ambient Size	$PM_{2.5}$, PM_{10}
Primary Findings	Average personal $PM_{2.5}$ exposure was similar to ambient $PM_{2.5}$ concentrations but much higher than average indoor concentrations. Personal, indoor, and outdoor $PM_{2.5}$ and PM_{10}, as well as the ratio PM2.5/PM10, were all significantly higher during the winter. Personal $PM_{2.5}$ and PM_{10} exposures were highest for the children in the study.

Lung et al. (2007, 156719)

Period	Weekdays between Nov 1998 and Feb 1999
Location	6 communities in Taiwan, China 2 in Taipei, 2 in Taichung, and 2 in Kaohsiung. Sites are industrial, commercial, residential and mixed.
Age Groups	18 to >70
Indoor Source	Being in kitchen, park, major boulevard, stadium, incense burning, household work, factory, environmental tobacco smoke, traffic, ventilation conditions
Personal Method	Personal Environmental Monitor with a SKC personal pump at 2 L/min, 37 mm Teflon filters
Personal Size	PM_{10}
Microenvironment Size	PM_{10}
Ambient Size	PM_{10}
Component(s)	None
Primary Findings	Outdoor rather than indoor levels contributed significantly to personal exposure. Important factors include time spend outdoors and on transportation, riding a motorcycle, passing by factories, cooking or being in the kitchen, incense burning at home.

Meng et al. . (2005, 081194)

Study Design	Evaluation of the use of central-site PM, rather than actual exposure, in PM epidemiology
Period	Summer 1999-spring 2001
Location	3 cities: Houston (TX), Los Angeles County (CA), and Elizabeth (NJ)
Population	NR
Age Groups	NR
Indoor Source	NR
Personal Method	MSP monitors on the front strap of the sampling bag near the breathing zone. Pump, battery, and motion sensor were on the hip or back.
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	EC, OC, S, Si
Primary Findings	Use of central-site $PM_{2.5}$ as an exposure surrogate underestimates the bandwidth of the distribution of exposures to PM of ambient origin.

Meng et al. (2005, 058595)

Study Design	RIOPA study matched indoor home & outdoor exposure assessment
Period	May-October (hot); November-April (cool); (1999-2001)
Location	Los Angeles County, CA; Elizabeth, NJ; Houston, TX
Population	Non-smoking homes
Indoor Source	Combustion (primary); atmospheric (secondary); sulfate, organics, nitrates; mechanically (abrasion) generated.
Personal Method	Filter (not specified)
Personal Size	NR
Microenvironment Size	Indoor home.; $PM_{2.5}$
Ambient Size	$PM_{2.5}$, outdoor home
Component(s)	Organic and elemental carbon; 24 elements (metals).
Primary Findings	The median contribution of ambient sources to indoor $PM_{2.5}$ using the mass balance approach was 56% for all study homes, 63% for California, 52% for New Jersey, and 33% for Texas.

Molnár et al. (2005, 156772)

Study Design	Indoor/outdoor exposure assessment related to domestic wood burning
Period	10 February to 12 March 2003
Location	Hagfors, Sweden
Population	Adult residents of Hagfors
Age Groups	NR
Indoor Source	NR
Personal Method	Integrated filter samples with a dichotomous virtual impactor to separate $PM_{10\text{-}2.5}$ from $PM_{2.5}$
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{10\text{-}2.5}$, $PM_{2.5}$
Ambient Size	$PM_{10\text{-}2.5}$, $PM_{2.5}$
Component(s)	BS, S, Cl, K, Ca, Mn, Fe, Cu, Zn, Br, Rb, Pb
Primary Findings	Wood burning made statistically significant contributions to personal exposure to K, Ca, and Zn. Cl, Mn, Cu, Rb, Pb, and BS were found to be potential personal exposures from wood smoke, but their association was not always statistically significant. S had no significant association with personal exposure to wood smoke.

Molnár et al. (2006, 156773)

Study Design	Cross-sectional
Period	Autumn and spring in 2002 and 2003
Location	Goteborg, Sweden,
Population	Persons living in urban settings
Age Groups	20 subjects 20-50 yr randomly selected from the population and 10 from departmental colleagues.
Indoor Source	NR
Personal Method	Integrated filter samples with cyclones for $PM_{2.5}$ and PM_1 cut points
Personal Size	$PM_{2.5}$ and PM_1
Microenvironment Size	NR
Ambient Size	NR
Component(s)	S, Cl, K, Ca, Ti, V, Mn, Fe, Ni, Cu, Zn, Br, Pb
Primary Findings	Personal exposure to Cl, K, Ca, Ti, Fe, and Cu in PM2.5 were significantly higher than outdoor and central site ambient concentrations, and personal exposure to Cl, Ca, Ti, Fe, and Br were also significantly higher than indoor levels. In most cases, indoor concentrations were not higher than outdoor concentrations.

Na and Cocker (2005, 156790)

Study Design	Human exposure assessment
Period	Sept. 2001-January 2002
Location	Mira Loma, CA
Population	Residential homes and a high school
Age Groups	NR
Indoor Source	Indoor EC (elemental carbon) concentrations primarily of outside origin; Indoor $PM_{2.5}$ significantly influenced by indoor OC (organic carbon) sources, including indoor smoking.
Personal Method	Integrated filter samples for $PM_{2.5}$
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	EC, OC
Primary Findings	Indoor $PM_{2.5}$ was significant influenced by indoor OC sources. Indoor EC sources were predominantly of outdoor origin.

Naumova et al. (2003, 089213)

Study Design	RIOPA Study-PAH partitioning indoor and outdoor pollutants to evaluate the hypothesis that outdoor air pollution contributed strongly to indoor air pollution.
Period	July 1999-June 2000
Location	Los Angeles, CA, Houston, TX, Elizabeth, NJ
Population	Houses
Age Groups	NR
Indoor Source	NR
Personal Method	Modified MSP Samplers, 37 mm quartz filter
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	OC, EC
Primary Findings	Both EC and OC were associated with gas/particle partitioning of PAHs, with EC being a better predictor. High correlation between EC and OC suggests that PAHs adsorb onto PM containing EC during combustion.

Nerriere et al. (2005, 089481)

Study Design	Exposure assessment with stratified sampling of children and adults in 3 environments: high traffic emissions, local industrial sources, and urban background.
Period	"Hot" season May-June and "cold" season Feb-Mar. Grenoble in 2001, Paris in 2002, Rouen in 2002-2003, Strasbourg 2003.
Location	Grenoble, Paris, Rouen, and Strasbourg, France
Population	Persons living, working, or going to school in 3 urban areas one highly exposed to traffic emissions, one influenced by local industrial sources, and a background urban environment. Industrial sources of pollution were present in each city.
Age Groups	6-13 yr and 20-71 yr. All non-smokers and not exposed to environmental tobacco smoke or industrial air pollution.
Indoor Source	NR
Personal Method	Rucksack with Harvard ChemPass
Personal Size	$PM_{2.5}$, PM_{10}
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$, PM_{10}
Copollutant(s)	NO_2
Primary Findings	The difference between ambient air concentrations and average total exposure is pollutant specific. $PM_{2.5}$ and PM_{10} concentrations underestimate population exposures across almost all cities, season, and age groups, but the opposite is true for NO_2.

Noullett et al (2006, 155999)

Study Design	Cohort
Period	5 February to 16 March 2001
Location	Prince George, British Columbia
Population	Children
Age Groups	10-12 yr
Indoor Source	NR
Personal Method	$PM_{2.5}$ Harvard Personal Environment Monitors ($HPEM_{2.5}$)
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	SO_4^{2-}, ABS (light absorbing carbon)
Primary Findings	Thermal inversions were associated with personal exposures as well as ambient $PM_{2.5}$ concentrations and likely caused observed spatial variability. However, ambient sampling locations were correlated in time. Similar observations were made for SO_4^{2-} and ABS.

Rojas-Bracho et al. (2004, 054772)

Study Design	Cohort study with repeated measures.
Period	Winter or summer of 1996-1997
Location	Boston, Massachusetts
Population	COPD patients
Age Groups	Adult
Indoor Source	Housecleaning, cooking, transport in motor vehicles, low-effort home activities, moderate-effort home activities, activities in public places, and resting or sleeping.
Personal Method	PEM
Personal Size	$PM_{2.5}$, PM_{10}, and $PM_{10-2.5}$
Microenvironment Size	$PM_{2.5}$, PM_{10}, & $PM10\text{-}2.5$
Ambient Size	NR
Component(s)	NR
Primary Findings	During both seasons, personal exposures were higher than indoor or outdoor means, except during the winter when indoor concentrations were higher than the personal or outdoor.

Rotko et al. (2002, 037240)

Study Design	European multi-city air pollution study
Period	Athens, Greece:26 January 1997–4 June 1998 Basel, Switzerland 3 February 1997–23 January 1998 Milan, Italy 10 March 1997–23 May 1998 Oxford, UK November 1998–7 October 1999 Prague, Czech Republic 3 June 1997–4 June 1998 Helsinki, Finland 26 September 1996–10 December 1997
Location	Athens, Greece; Basel, Switzerland; Milan, Italy; Oxford, UK; Prague, Czech Republic; Helsinki, Finland
Population	Adults
Age Groups	25-55 yr
Indoor Source	NR
Personal Method	Integrated 48-h $PM_{2.5}$ filter samples
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Copollutant(s)	NO_2
Primary Findings	Personal $PM_{2.5}$ and NO_2 levels were associated with subjects' level of annoyance. Highest annoyance levels occurred while in traffic.

Sanderson and Farant (2004, 156942)

Study Design	Indoor and outdoor air monitoring of PAH. Investigate the relationship between indoor and outdoor PAH.
Period	NR
Location	Canada
Population	Residential homes in neighborhoods around aluminum smelting plant
Age Groups	NR
Indoor Source	NR
Personal Method	Indoor quartz filter sample
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	NR
Component(s)	4-6 ring PAHs on indoor particle
Primary Findings	Indoor concentration of 4-6-ring PAH were linked to outdoor industrial sources in residences without any major indoor source, but with industrial facility as the main outdoor source. This study suggests that simultaneous measurements of indoor and outdoor concentrations of PAH >4 rings predominantly associated with fine PM could provide useful estimates of particle infiltration efficiency.

Sarnat et al. (2006, 089166)

Study Design	Outdoor-indoor pollutant infiltration, occupied residences
Period	July 28, 2001-February 25, 2002
Location	Los Angeles, CA
Population	NR
Indoor Source	Yes; cleaning, cooking, home ventilation (open windows/doors), kitchen fans, air conditioner/heating usage, number of occupants, nearby roadways
Personal Method	NR
Personal Size	NR
Microenvironment Size	$PM_{2.5}$, Particle number
Ambient Size	$PM_{2.5}$
Component(s)	BC (nonvolatile component); NO_3 (volatile component)
Primary Findings	Infiltration rate for $PM_{2.5}$ was intermediate, while BC was highest and NO_3 lowest. Infiltration rate varied with particle size, air exchange rate, outdoor NO_3. $PM_{2.5}$ infiltration was lowest for volatile components. Outdoor volatile $PM_{2.5}$ components may be less representative of indoor exposure to volatile $PM_{2.5}$ of ambient origin. Outdoor nonvolatile $PM_{2.5}$ components may be more representative of indoor exposure to nonvolatile $PM_{2.5}$ of ambient origin.

Sarnat et al. (2006, 090489)

Study Design	Personal and ambient exposure assessment
Period	June 14-August 18 (summer); Sep 24-Dec 15 (fall), 2000
Location	Steubenville, OH
Population	Non-smoking, older adults
Age Groups	NR
Personal Method	Integrated filter gravimetric measurement
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	SO_4^{2-}; EC
Primary Findings	24-h ambient measurements are more representative of personal particle exposure than gases, and ventilation is an important exposure modifier.

Sarnat et al. (2005, 087531)

Study Design	Time-series epidemiologic study
Period	Summer 1999 and winter 2000
Location	Boston, MA. Comparisons to a previous study in Baltimore are also made.
Population	School children and seniors
Age Groups	NR
Indoor Source	$PM_{2.5}$
Personal Method	NR
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	SO_4,
Copollutant(s)	O_3, NO_2, SO_2
Primary Findings	Substantial correlations between ambient $PM_{2.5}$ concentrations and corresponding personal exposures. Summertime gaseous pollutant concentrations may be better surrogates of personal $PM_{2.5}$ exposures (especially personal exposures to $PM_{2.5}$ of ambient origin) than they are surrogates of personal exposures to the gases themselves.

Shalat et al. (2007, 156971)

Study Design	Indoor home exposure assessment; sampling technology demonstration
Period	Winter heating season
Location	Residential home
Population	Children
Age Groups	Pre-toddler (6- to 12-month-old) children
Indoor Source	NR
Personal Method	Integrated filter and real-time nephelometer at floor height and at a height of 110 cm
Personal Size	TSP, inhalable PM
Microenvironment Size	NR
Ambient Size	NR
Copollutant(s)	NR
Primary Findings	The study results suggest that young children are exposed to more inhalable PM and TSP because PM becomes resuspended from the floor with motion.

Shao et al. (2007, 156973)

Study Design	Exposure assessment
Period	July and Winter 2003
Location	Beijing, China
Population	General population
Age Groups	NR
Indoor Source	NR
Personal Method	PM_{10} measured with integrated filter samples
Personal Size	PM_{10}
Microenvironment Size	PM_{10}
Ambient Size	PM_{10}
Component(s)	NR
Primary Findings	Plasmid scission assay, coupled with the image analysis, can be used to evaluate the relationship between particle physico-chemistry and toxicity.

Shilton et al. (2002, 049602)

Study Design	Respirable particulates inside and outside of a building were collected and compared
Period	24-h sampling from 12:45 pm Mondays to Fridays between 9/19/00 to 5/01/01
Location	Wolverhampton city center, University of Wolverhampton, UK
Population	NR
Indoor Source	Mn,Al, NO_3, Cl^- (wind-blown dust), Cu and Zn^-
Personal Method	Active sampling using Casella sampler (filter)-
Personal Size	Respirable PM
Microenvironment Size	Respirable PM
Ambient Size	Respirable PM
Component(s)	NO_3^-, metals (Zn, Cu, Mn, Al), SO_4^{2-}, Cl^-
Primary Findings	The indoor particulate concentration was driven by ambient concentration, and meteorological-induced changes in ambient PM were detected indoors.

Strand et al. (2007, 157018)

Study Design	Cohort
Period	Winter of 1999-2000 and winter of 2000-2001
Location	Denver, Colorado
Population	Asthmatic children
Indoor Source	NR
Personal Method	Modeling/extrapolation from fixed-site ambient monitoring (multiple methods)
Personal Size	NR
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	Using modeled or extrapolated personal ambient PM exposure results in a deattenuation of decrements in FEV_1 associated with PM exposure, relative to use of fixed-site ambient monitoring PM levels. Associations between FEV1 decrements and the various estimation procedures (modeling and extrapolation) were similar to each other.

Tang et al. (2007, 091269)

Study Design	Cohort Study
Period	12/2003-2/2005
Location	Sin-Chung City, Taiwan
Population	Asthmatic children
Age Groups	6-12 yr
Indoor Source	No
Personal Method	Portable particle monitor; DUSTcheck Portable Dust Monitor, model 1.108, GRIMM Labortechnik Ltd., Germany
Personal Size	PM_{10}, $PM_{2.5}$, PM_1, $PM_{10\text{-}2.5}$, $PM_{2.5\text{-}1}$
Microenvironment Size	NR
Ambient Size	PM_{10}, $PM_{2.5}$, $PM_{10\text{-}2.5\text{-}}$
Component(s)	NR
Primary Findings	Results of linear mixed-effect model analysis suggested that personal PM data was more suitable for the assessment of change in children's PEFR than ambient monitoring data.

Thornburg et al. (2004, 157052)

Study Design	PM exposure studies
Period	RTP: Summer 2000-spring 2001 Tampa: October-November 2002
Location	Research Triangle Park (RTP), NC and Tampa, FL
Population	Residential home occupants
Age Groups	NR
Indoor Source	Resuspension of PM_{10} from a carpet and cooking
Personal Method	Harvard impactors and PEMs, MIE pdr1000 nepholometer
Personal Size	$PM_{2.5}$, PM_{10}
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$, PM_{10}
Component(s)	NR
Primary Findings	The association of duty cycle with indoor-outdoor (I/O) ratio was confounded by the short time span of ventilation system operation and the presence of strong indoor sources.

Toivola et al. (2002, 026571)

Study Design	Random sample of teachers
Period	Nov 1998-Mar 1999 and Nov-Dec 1999
Location	2 cities in eastern Finland
Age Groups	Adult
Indoor Source	Fungi, bacteria
Population	Elementary school teachers
Personal Method	Button inhalable aerosol sampler
Personal Size	Particle Mass; BS
Microenvironment Size	Particle Mass; BS
Ambient Size	NR
Component(s)	Total fungi, total bacteria, viable fungi, viable bacteria
Primary Findings	Personal BS exposure correlated with both home and work BS exposures. BS concentrations explained best the variation of particle mass in personal and home concentrations.

Trenga et al. (2006, 155209)

Study Design	Panel study with repeated measures
Period	3 sampling periods Oct 1999-Aug 2000, Oct 2000-May 2001, Oct 2001-Feb 2002
Location	Seattle, Washington
Population	Adults with and without COPD and children with asthma
Age Groups	adults ages 56-89 and children ages 6-13
Indoor Source	NR
Personal Method	Carrying personal monitor (Harvard Personal Environmental Monitor for $PM_{2.5}$)
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{10-2.5}$, $PM_{2.5}$ for residential outdoor, $PM_{2.5}$ for central site
Component(s)	NR
Primary Findings	FEV_1 decrements associated with 1-day lagged central site $PM_{2.5}$ in adult subjects with COPD. Associations between PM and lung function decrements were significant only in asthmatic children not receiving anti-inflammatory medication.

Turpin et al. (2007, 157062)

Study Design	RIOPA Study 24-h integrated indoor, outdoor, and personal samples collected in 3 cites.
Period	Summer 1991-spring 2001
Location	Elizabeth, NJ, Houston, TX, and Los Angeles County, CA
Population	309 adults and 118 children (89-18)
Indoor Source	NR
Personal Method	PEM on the front strap of a harness near the breathing zone. The bag on the hip contained the pump, battery pack, and motion sensor
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$, in the main living area (not kitchen)
Ambient Size	$PM_{2.5}$, in the front or back yard
Component(s)	18 volatile organics, 17 carbonyl, $PM_{2.5}$ mass and >23 $PM_{2.5}$ species, organic carbon, elemental carbon, and PAHs
Primary Findings	The best estimate of the mean contribution of outdoor to indoor $PM_{2.5}$ was 73% and the outdoor contribution to personal was 26%.

Vallejo et al. (2006, 157081)

Study Design	Panel study
Period	4/2002-8/2002
Location	Mexico City, Mexico
Population	Health young, non-smoking adults
Age Groups	Mean age 27 yr
Indoor Source	NR
Personal Method	pDR nephelometric method
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	NR
Component(s)	NR
Primary Findings	The descriptive analysis showed that overall outdoor median concentration of $PM_{2.5}$ was higher than the indoor concentration. In the indoor microenvironment, the highest concentrations occurred in the subway followed by the school, and the lowest was at home. The outdoor microenvironment with the highest concentrations was the public transportation (bus), while the automobile had the lowest. It was found that $PM_{2.5}$ concentration levels had a circadian-like behavior probably related to an increase in the population daily activities during the morning hours, which decrease in the evening, especially at indoor microenvironments. The Center city area was found to have the highest concentrations of $PM_{2.5}$.; Multivariate analysis corroborated that $PM_{2.5}$ concentrations are mainly determined by geographical locations and hour of the day, but not by the type of microenvironment.

van Roosbroeck et al. (2006, 090773)

Study Design	Personal exposure assessment, effect of traffic-related pollutants
Period	March-June 2003
Location	Amsterdam, The Netherlands
Population	Schoolchildren
Age Groups	9-12 yr
Indoor Source	ETS, cooking
Personal Method	Integrated filter gravimetric measurement. Light absorbance.
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	$PM_{2.5}$
Component(s)	Absorbance
Primary Findings	Children living near busy roads had 35% higher personal exposure to ‘soot’ than children living in urban background locations.

Vinzents et al. (2005, 087482)

Study Design	Panel study
Period	3/2003-6/2003
Location	Copenhagen, Denmark
Population	Healthy young adults
Age Groups	Mean age = 25 yr
Indoor Source	No
Personal Method	Condensation particle counters
Personal Size	UFP (10-100 nm)
Microenvironment Size	UFP (10–100 nm)
Ambient Size	PM_{10}
Primary Findings	UFP exposure predicted oxidative DNA damage.

Wallace and Williams (2005, 057485)

Study Design	Cohort
Period	2000-2001
Location	Raleigh, North Carolina
Population	African-American persons with elevated risk from exposure to particles.
Age Groups	NR
Indoor Source	NR
Personal Method	PEM $PM_{2.5}$ monitor
Personal Size	$PM_{2.5}$
Microenvironment Size	Indoors $PM_{2.5}$
Ambient Size	Outdoors near residence $PM_{2.5}$ $PM_{2.5}$
Component(s)	S
Primary Findings	Using outdoor particles to determine the effect on health is not accurate. The infiltration factor is a good estimator for personal exposure. Indoor and outdoor measurements of sulfur could be used in the absence of personal exposure measurement to estimate the contribution of outdoor fine particles to personal exposures.

Wallace et al. (2006, 088211)

Study Design	Time series continuous monitoring of subjects with controlled hypertension or implanted defibrillators were monitored for 7 consecutive days in 4 seasons.
Period	2000-2001
Location	North Carolina
Population	Health-compromised adults, non-smokers
Age Groups	Adults
Indoor Source	Cooking, cleaning, personal care, smoking
Personal Method	PEM
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$; Indoor and outdoor
Ambient Size	NR
Component(s)	NR
Primary Findings	Use of continuous particle measuring instruments allowed more precise identification of sources, frequency and magnitude of short-term peaks, and more accurate calculation of individual personal clouds.

Wang et al. (2006, 157108)

Study Design	Exposure assessment, identification of sources of outdoor and indoor PM and trace elements
Period	Aug 4 -Sep 10, 2004
Location	Guangzhou, China
Population	4 hospitals
Age Groups	NR
Indoor Source	NR
Personal Method	No personal exposure assessment was conducted.
Personal Size	NR
Microenvironment Size	PM_{10}, $PM_{2.5}$
Ambient Size	PM_{10}, $PM_{2.5}$
Component(s)	Na, Al, Ca, Fe, Mg, Mn, Ti, K, V, Cr, Ni, Cu, Zn, Cd, Sn, Pb, As, Se
Primary Findings	High correlation between $PM_{2.5}$ and PM_{10} suggest that they came from similar emission sources. Outdoor infiltration could lead to direct transportation of PM indoors. Human activities and ventilation types could also influence indoor PM. levels.

Ward et al. (2007, 157112)

Study Design	Indoor air sampling to determine size fractionated concentrations of PM, OC, EC, and total carbon
Period	Jan-Mar 2005
Location	Libby, Montana
Population	Children exposed to wood-burning stoves in elementary and middle schools
Indoor Source	Burning wood in stoves for heating
Personal Method	NR
Personal Size	NR
Microenvironment Size	PM >2.5, 1.0-2.5, 0.5-1.0, 0.25-0.5, and < 0.25 µm
Ambient Size	PM >2.5, 1.0-2.5, 0.5-1.0, 0.25-0.5, and < 0.25 µm
Component(s)	OC and EC
Primary Findings	Total measured PM mass concentrations were much higher inside the elementary schools, with particle size fraction (>2.5, 0.5-1.0, 0.25-0.5, and < 0.25 mm) concentrations between 2 and 5 times higher when compared to the middle school. The 1.0-2.5 mm fraction had the largest difference between the two sites, with elementary school concentrations nearly 10 times higher than the; middle school values.

Weisel et al. (2005, 157131)

Study Design	Matched indoor, outdoor, and personal concentrations in proximity to pollution sources.
Period	May 1999-Feb 2001
Location	Elizabeth, NJ, Houston, TX, and Los Angeles County, CA
Population	urban children and adults
Age Groups	Children and adults (6-89 yr)
Indoor Source	Age of house, recent renovations (< 1 yr), type of home (single, multiple family), attached garage, carpet indoors, local pollution sources.
Personal Method	PEM on a harness with inlet near breathing zone.
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	Personal $PM_{2.5}$ was significantly higher than indoor and outdoor $PM_{2.5}$ concentrations.

Wichmann et al. (2005, 086240)

Study Design	Exposure assessment
Period	November 29, 1993-March 30, 1994; October 17, 1994-December 22, 1994
Location	Amsterdam, The Netherlands
Population	Adults and schoolchildren living near high-traffic or low-traffic roads
Age Groups	Adults (50-70 yr), schoolchildren (10-12 yr)
Indoor Source	NR
Personal Method	Personal impactor
Personal Size	PM_{10}
Microenvironment Size	PM_{10}
Ambient Size	PM_{10}
Component(s)	Absorbance coefficient measurements
Primary Findings	Found tentative support for using type of road as a proxy for indoor and personal exposure to traffic-related absorbance PM.

Williams et al. (2003, 053338)

Study Design	Cohort study, longitudinal
Period	Summer 2000, fall 2000, winter 2001, and spring 2001
Location	Raleigh and Chapel Hill, North Carolina
Population	Elderly persons
Age Groups	> 50 yr
Indoor Source	Occasional ETS
Personal Method	Integrated filter samples
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$; PM_{10}; $PM_{10-2.5}$
Ambient Size	$PM_{2.5}$; PM_{10}; $PM_{10-2.5}$
Component(s)	NR
Primary Findings	When comparing cohorts, there was no statistically significant difference between $PM_{2.5}$ exposure. Little spatial variability was observed regarding $PM_{2.5}$ concentrations; this was observed to a lesser extent for PM_{10} as well.

Wilson and Brauer (2006, 088933)

Study Design	Exposure assessment
Period	April-September 1998
Location	Vancouver, Canada
Population	Subjects with physician-diagnosed COPD
Age Groups	54-86-years-old
Indoor Source	No
Personal Method	Personal integrated filter gravimetric measurement; TEOM outdoor ambient
Personal Size	$PM_{2.5}$
Microenvironment Size	NR
Ambient Size	NR
Component(s)	SO_4^{2-}
Primary Findings	It was observed that ambient $PM_{2.5}$ exposure, estimated with the SO_4^{2-} method, accounted for 71% of measured ambient concentration and 44% of measured total personal exposure. No correlation between nonambient exposure and ambient concentration was observed.

Wu et al. (2006, 179950)

Study Design	Panel study
Period	9/3/2002-11/1/2002
Location	Pullman, WA
Population	Asthmatic adults
Age Groups	18-52 yr
Indoor Source	No
Personal Method	Co-located Harvard Personal Environmental Monitors (HPEM2.5; Harvard School of Public Health, Boston, MA)\
Personal Size	PM2.5
Microenvironment Size	PM2.5
Ambient Size	PM2.5
Component(s)	Levoglucosan (LG); Elemental Carbon (EC); Organic Carbon (OC)
Primary Findings	The authors observed significant variability between subjects for burning and nonburning episodes. The authors postulated that activity patterns contribute to this variability and that central-site measurements of LG might not be a good surrogate for biomass combustion smoke exposurefor this reason.

Wu et al. (2005, 086397)

Study Design	Panel study
Period	1999-2000
Location	Alpine, CA
Population	Asthmatic children
Age Groups	9-17 yr
Indoor Source	NR
Personal Method	pDR
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	NR
Primary Findings	Personal exposure was higher than those at fixed sites. Subjects received only 45.0% of their exposure indoors at, although they spent more than 60% of their time there. In contrast, 29.2% of their exposure was received at school where they spent only 16.4% of their time. Thus, exposures in microenvironments with high PM levels where less time is spent can make significant contributions to the total exposure.

Yeh and Small (2002, 040077)

Study Design	Comparative assessment of AME and IES models
Period	1997 (364 days) spring March-May, summer June-August, Fall September-November, winter December-February
Location	Los Angeles County, CA
Population	General population; ETS and non-ETS Homes
Age Groups	NR
Indoor Source	Indoor Cooking, ETS, Other sources and unexplained particulates that maybe generated with engaging in various activities
Personal Method	NR
Personal Size	PM_{10} $PM_{2.5}$
Microenvironment Size	NR
Ambient Size	PM_{10} $PM_{2.5}$
Component(s)	NR
Primary Findings	Adjusting from outdoor concentrations to personal exposures and correcting dose-response bias produce nearly equal results. Roughly the same premature mortalities associated with short-term exposure to both ambient $PM_{2.5}$ and PM_{10} are predicted by both models

Yip et al. (2004, 157166)

Study Design	A panel study with repeated measures with personal & home monitoring for 8 2-week Periods. Children were stratified into smoking and non-smoking households.
Period	2000-2001
Location	Detroit, Michigan
Population	School-age children with asthma
Age Groups	7-11 yr
Personal Method	PEM in a backpack
Personal Size	PM_{10}
Microenvironment Size	PM_{10}; indoor at home & indoor at school
Ambient Size	PM_{10}
Component(s)	NR
Primary Findings	Personal PM concentrations were significantly correlated with home environment (r = 0.38 to 0.70), with the strongest relationships in home with non-smokers.

Zhao et al. (2006, 156181)

Study Design	Aerosol source apportionment under four environments (personal, residential indoor, residential outdoor and ambient) to evaluate the relationship between different environments through exposure analysis, and to demonstrate the utility of the combined receptor model on air quality studies of various environments.
Period	June 2000 to May 2001
Location	Raleigh and Chapel Hill, NC
Population	NR. People with respiratory ailments most likely.
Age Groups	NR
Indoor Source	4 main sources to residential indoor PM Cu-factor mixed with indoor soil, secondary sulfate, Personal care and activity, ETS and its mixture
Personal Method	PEM and HI
Personal Size	NR
Microenvironment Size	NR
Ambient Size	NR
Component(s)	SO_4^{2-} , OC, EC, and trace elements
Primary Findings	Secondary SO_4^{2-} and vehicle emissions were significant contributors of personal PM exposure and residential indoor PM concentrations.

Zhao et al. (2007, 156182)

Study Design	Comprehensive analysis of the sources of PM_{15} exposure on children with moderate to severe asthma in urban-poor settings.
Period	Two winter periods (October 2002-March 2003 and October 2003-March 2004)
Location	Elementary school for children with significant asthma, Denver, CO
Population	Schoolchildren in urban-poor settings suffering from moderate to severe asthma
Age Groups	6-13 yr (60% in the range 10-13 yr, rest in the range 6-9 yr)
Indoor Source	Yes, House cleaning compounds, and smoking were identified as primary internal sources.
Personal Method	PEM
Personal Size	$PM_{2.5}$
Microenvironment Size	$PM_{2.5}$
Ambient Size	$PM_{2.5}$
Component(s)	EC, Cl, Si, NO_3
Primary Findings	Four external sources and three internal sources were resolved in this study. Secondary nitrate and motor vehicle were two major outdoor $PM_{2.5}$ sources. Cooking was the largest contributor to the personal and indoor samples. Indoor environmental tobacco smoking also has an important impact on the composition of the personal exposure samples.

Zhu et al. (2005, 157191)

Study Design	4 apartments near the freeway were monitored at 2 times for 6 consecutive days, 24 h per day. Subjects did not enter the bedrooms where the samplers were, no cooking, cleaning, children, or pets.
Period	Oct. 2003-Dec. 2003 and Dec. 2003-Jan. 2004
Location	Los Angles, CA
Population	Urban Populations near major freeways.
Age Groups	NR
Indoor Source	NR
Personal Method	NR
Personal Size	Indoor and Outdoor ultrafine particles (6-220 nm)
Microenvironment Size	NR
Component(s)	CO
Primary Findings	The size distributions of indoor aerosols showed less variability than the adjacent outdoor aerosols. Indoor to outdoor ratios for ultrafine particle concentrations depended strongly on particle size. I/O ratios were dependent on the indoor ventilation mechanisms applied. Size-dependent particle penetration factors and deposition rates were predicted from data by fitting a dynamic mass balance model.

Zöllner et al. (2007, 157192)

Study Design	Exposure assessment
Period	Winter Period of 2005 and 2006
Location	Baden-Wuerttemberg, Germany
Population	School children
Age Groups	NR
Personal Method	NR
Personal Size	NR
Microenvironment Size	They only reported concentrations for $PM_{2.5}$. PM ranging in size from 0.02 to >20 μm were collected and analyzed but only $PM_{2.5}$ concentration were reported.
Ambient Size	They only reported concentrations for $PM_{2.5}$. PM ranging in size from 0.02 to >20 μm were collected and analyzed but only $PM_{2.5}$ concentration were reported.
Primary Findings	The impaction of PM was strongly influenced by specific weather conditions. Time resolution of measurements in classrooms showed variation in particle concentration depending on the type of building and indoor activities. E'[Concentrations of very small particles indoors and in ambient air measured by condensation particle counter were influenced by traffic emissions.

Table A-59. Examples of studies showing developments with UFP sampling methods since the 2004 PM AQCD.

Reference	PM Size Ranges	PM Constituents	Instruments	Study Description
Biswas et al. (2005, 150694)			CPC (water)	Water-based CPC performance evaluation.
Feldpausch et al. (2006, 155773)	20-100 nm	Carbonaceous aerosols	DS with CPC, compared with DMA	The DS with CPC compared fairly well with the DMA for particle sizes up to 40 nm with 20-40% underestimation depending on discharge frequency settings. The DS sampling period is 3-5 s in comparison with the 1 min scanning time of the DMA.
Hering et al. (2005, 155838)			CPC (water)	Water-based CPC performance evaluation.
Hermann et al. (2007, 155840)	3-40 nm	Ag, NaCl	CPC (water and butanol)	Roughly 95% collection efficiency for d >5 nm for TSI models 3776 and 3786, 95% efficiency for d >20 nm for model 3775, near 90% efficiency for d>20 nm for model 3785, near 90% efficiency for d >25 nm for model 3772.
Kinsey et al. (2006, 130654)	10 nm-5 μm	DE	TEOM, SMPS, CPC, DustTrak, E-BAM, ELPI, integrated filter samples	TEOM compared best with gravimetric filter among mass concentration analyzers, ELPI and SMPS comparable for differential number distribution but ELPI not useful for gravimetric analysis because mass is not significant at small end of distribution.
Kulmala et al. (2007, 097838)			CPC	Changing temperature difference between saturator and condenser within CPC allowed for differences in cut-off diameters.
Kulmala et al. (2007, 155911)	2-20 nm	Atmospheric aerosol, Ag	Battery of CPCs (water, butanol, n-butanol)	Used the battery to discriminate between water-soluble, water-insoluble, butanol-soluble, and butanol-insoluble nucleation-mode particles.
Ntziachristos and Samaras (2006, 116722)	7 nm-1 μm	Automobile exhaust	5 instruments used simultaneously to reduce uncertainty: Teflon-coated filter downstream of constant volume sampling, ELPI with thermodenuder, CPC, SMPS, diffusion charger	Use of four reduced variables combining output from all instruments (ratio of particle number concentration from CPC and ELPI, estimated mean geometric mobility diameter from signal of diffusion charger and number concentration from CPC, ratio of signal of diffusion charger to constant volume sampler mass, ratio of constant volume sampler mass to volume collected by ELPI) resulted in identification of clear outliers and factors related to driving and fuel properties rather than measurement errors.
Olfert et al. (2008, 156004)	30-100 nm	NaCl, ambient	FIMS (compared with SMPS)	Particle number concentrations reported by the FIMS were 8-23% higher than the SMPS using an inversion technique designed to correct for particle residence time in the FIMS, which operates at 0.1 s resolution.
Petäjä et al. (2006, 156021)			CPC (water)	Water-based CPC performance evaluation.
Winkler et al. (2008, 156160)	1.5-4 nm	Tungsten oxide	CPC (n-Propanol)	Authors remove excess charge on particles with ion trap to detect particles down to ~ 1 nm (by eliminating electrostatic attraction to agglomerate).

Table A-60. Summary of in-vehicle studies of exposure assessment.

Reference	Study Design	Mode of Transport	Exposures	Primary Findings
Briggs et al. (2008, 156294)	UFP (P-Trak), PM_{10}, $PM_{2.5}$, and PM_1 (OSIRIS light scatter) were operated in a car while driving or walking on one of 48 routes in London. Trips ranged 1.5-15 min by car and were repeated up to 5 times to improve statistics. Study Period: Weekdays in May and June 2005.	Car Walking	Units: PM_1-PM_{10} (µg/m^3), UFP (p cm^{-3}) Avg Car Exposure: PM_{10} 5.87 (3.09) $PM_{2.5}$ 3.01 (1.10) PM_1 1.82 (1.10) UFP 21639 (14379) Avg Walking Exposure: PM_{10} 27.56 (13.16) $PM_{2.5}$ 6.59 (3.12) PM_1 3.37 (3.40) UFP 30334 (17245)	In-car concentrations of $PM_{2.5}$, PM_1, and UFP correlated well with walking concentrations (R = 0.806, 0.800, 0.799 respectively). Avg walking concentrations were 1.4-4.7 times higher than average in-car concentrations. Cumulative walking exposures (not shown here) were 4.4-15.2 times higher than those in cars, likely resulting from longer transit times for walking.
Diapouli et al. (2007, 156397)	UFP (CPC) concentrations were measured at school, residential, and in-vehicle environments in Athens, Greece. Study Period: school hours, Nov 2003-Feb 2004 and Oct-Dec 2004	Car	15-min median (1000p/cm^3): School indoor 13.6 School outdoor 16.6 Residence indoor 11.2 Residence outdoor 24.0 In-vehicle 78.0	In-vehicle UFP concentrations were roughly 3.5-7 times higher than school or residence concentrations. Indoor concentration diel patterns were also shown to follow outdoor levels, which suggests that indoor levels are of outdoor origin.
Fruin et al. (2008, 097183); Westerdahl et al. (2005, 086502) [Note: same data presented.]	On-road zero emissions vehicle driven on 33-mi arterial road and 75-mi freeway measured UFP (CPCs, SMPS, EAD), BC (aethalometer), NOX (chemiluminescence), PM-bound PAHs (UV-photoionization), and CO (Q-Trak). DVD analysis of traffic density and car speed. Study Period: Feb-Apr 2003 for 2- to 4-h periods.	Car	Arterial range of medians: UFP (1000p/cm^3) 13-43 $PM_{2.5}$ (µg/m^3) 7.9-45 BC (µg/m^3) 0.74-3.3 Freeway range of medians: UFP (1000p/cm^3) 47-190 $PM_{2.5}$ (µg/m^3) 25-110 BC (µg/m^3) 2.4-13	Measurements of freeway UFP, BC, PM-bound PAH, and NO_x concentrations were roughly one order of magnitude higher than ambient measurements. Multiple regression analysis suggests these concentrations were a function of truck density and total truck count. (Only PM measurements reported here).
Gomez-Perales et al. (2004, 054418)	$PM_{2.5}$ (personal filter pump), CO (T15 electrochemical cell), and benzene (canister) were measured on transit routes, and $PM_{2.5}$ filters were analyzed for mass, OC/EC, SO_4^{2-}, NO_3-, and trace metals. Study period: 3-h morning and evening rush hour May-June 2002	Bus Minibus Metro	$PM_{2.5}$ (µg/m^3): Bus 68 Minibus 71 Metro 61	Generally, $PM_{2.5}$ concentration was higher in the morning than evening rush hour, but variability was higher for minibuses than other modes of transport. Wind speed was found to be associated with $PM_{2.5}$ concentration on minibuses.

Reference	Study Design	Mode of Transport	Exposures	Primary Findings
Gomez-Perales et al. (2007, 138816)	$PM_{2.5}$ (personal filter pump), CO (T15 electrochemical cell), and benzene (canister) were measured on transit routes, and $PM_{2.5}$ filters were analyzed for mass, OC/EC, SO_4^{2-}, NO_3^-, and trace metals. Study period: 3-h morning and evening rush hour Jan-March 2003	Bus Minibus Metro	Units: $PM_{2.5}$ mass ($\mu g/m^3$), components (% of mass) Bus: $PM_{2.5}$ 20-58 $(NH_4O_3$ 5-8 $(NH_4)_2SO_4$ 10-18 OC 17-39 EC 8-20 Crustal 15-18 Non-crustal 2-3 Unknown 6-24 Minibus: $PM_{2.5}$ 25-55 $(NH_4O_3$ 4-13 $(NH_4)_2SO_4$ 7-22 OC 22-37 EC 9-19 Crustal 12-13 Non-crustal 3-3 Unknown 4-26 Metro: $PM_{2.5}$ 24-41 $(NH4O_3$ 5-8 $(NH4)2SO_4$ 10-21 OC 35-42 EC 9-13 Crustal 10-16 Non-crustal 2-4 Unknown 5-20	Buses and minibuses had similar concentration levels for $PM_{2.5}$ mass, and metro exposures were lower. CO and benzene concentrations were higher on minibuses than buses. OC was the largest PM constituent for all modes of transport. Measured concentrations were higher in the morning than in the evening rush hour periods. Maximum historical wind speeds (1995-2003) appeared to be inversely associated with measured concentration.
Gulliver and Briggs (2004, 053238)	PM_{10}, $PM_{2.5}$, and PM_1 sampled (OSIRIS light-scatter devices) in a car while driving or walking on northern corridor of Northhampton UK. Study Period: 1-h interval of morning and evening rush hour during Winter 1999-2000.	Car Walk	Walking concentrations, Units: $\mu g/m^3$ Walk, Car, Background PM_{10} 38.2,43.2, 26.6 $PM_{2.5}$ 15.1, 15.5 PM_1 7.1, 7.0	In-car PM_{10} concentrations were elevated compared with walking and background. $PM_{2.5}$ and PM_1 concentrations were comparable for walking and background. Periods of elevated $PM_{2.5}$ compared with PM_{10} generally corresponded to times when SO_4^{2-} levels were also high.
Gulliver and Briggs (2007, 155814)	TSP, PM_{10}, $PM_{2.5}$, and PM_1 sampled (OSIRIS light-scatter devices) in a car while driving or walking on one of 48 routes in London. Trips ranged 1.5-15 min by car and were repeated up to 4 times to improve statistics. Study Period: Jan-Mar 2005.	Car Walk	Mean concentrations, Units: $\mu g/m^3$ Walk, Car, Background TSP-PM_{10} 19.1 (19.8) 18.2 (18.0) 4.9 (5.1) $PM_{10-2.5}$ 22.1 (22.8) 15.1 (14.2) 10.0 (9.0) $PM_{2.5}$ -1 10.9 (10.4) 8.3 (8.4) 7.6 (7.1) PM_1 4.8 (3.4) 2.9 (2.6) 4.2 (2.4)	Walking exposures larger than car and background, and car exposures were generally larger than background except for PM_1. Peak exposures during walking were significantly higher than peak in-car exposures.
Rossner et al. (2008, 156927)	Measured $PM_{2.5}$ exposure of 50 city bus drivers and 50 controls in Prague, Czech Republic using personal samplers (type not specified) and VOCs using passive samplers. $PM_{2.5}$ filters analyzed for c-PAHs. Focus of study is oxidative stress biomarkers in drivers. Study period: winter 2005, summer 2006, winter 2006.	Bus	Units: ng/m^3 Winter 2005: Bus Control c-PAH 7.1 (3.7) 9.4 (5.5) B[a]P 1.3 (0.7) 1.8 (1.0) Smmer 2006: Bus Control c-PAH 1.8 (0.5) 2.0 (0.8) B[a]P 0.2 (0.1) 0.3 (0.2) Wnter 2006: Bus Control c-PAH 5.4 (3.5) 4.1 (1.7) B[a]P 1.0 (0.5) 0.8 (0.4)	c-PAH and B[a]P exposure to bus drivers was significantly higher in Winter 2006, but control exposure was significantly higher in Winter 2005 for c-PAH and B[a]P and in summer 2006 for c-PAH. No significant difference in VOC exposure between bus drivers and controls was observed. Oxidative stress markers were significantly higher in bus drivers than controls for all seasons.

Reference	Study Design	Mode of Transport	Exposures	Primary Findings
Sabin et al. (2005, 088300)	BC (aethalometer), particle-bound PAH (UV-photoionization), and NO (luminol reaction) were measured on 3 diesel school buses, 1 diesel school bus with a particle trap, and one compressed gas bus during before- and after-school commutes. Study Period: May-June 2002.	School bus (diesel, diesel with particle trap (TO), compressed gas (CNG))	In-bus mean concentration Units: BC ($\mu g/m^3$) PAH (ng/m^3) Windows closed: BC PAH Ambient: 2.5,27 CNG:2.3, 57 TO: 7.1, 190 Diesel:11, 290 Windows open: BC PAH Ambient: 1.9,26 CNG:1.5, 43 TO: 2.3, 42 Diesel: 3.9, 58	Mean concentrations on diesel buses without newer emissions control technologies were 2-4.4 times higher than background. On buses with particle traps, concentrations were 1.2-2.5 times higher than background, while concentrations on compressed gas-fueled school buses were actually lower than background.

Unadjusted mixed-model results demonstrated that ambient monitors are more likely to underestimate than overestimate exposure to many of the TEs that are suspected to play a role in the causation of air pollution related health effects. These data also support the conclusion that TE exposures are more likely to be underestimated in the lower income and centrally located PHI community than in the comparitively higher income BC K community. Within the limits of statistical power for this sample size, the adjusted models indicated clear seasonal and community related effects that should be incorporated in long-term exposure estimates for this population.
Brunekreef et al. (2005, 090486)	Personal, Micro & Ambient: $PM_{2.5}$	NO_3^-	Mean (SD), units = ng/m^3: Amsterdam: Personal 1389(1965) Indoor 1348(1843) outdoor 4063(4435) Helsinki: Personal 161(202) Indoor 267(215) Outdoor 1276(1181)	In both cities, personal and indoor $PM_{2.5}$ were lower than highly correlated with outdoor concentrations. For most elements, personal and indoor concentrations were also highly correlated with outdoor concentrations.
Brunekreef et al. (2005, 090486)	Personal, Micro, and Ambient: $PM_{2.5}$	SO_4^{2-}, NO_3^-	Mean, units = $\mu g/m^3$: SO_4^{2-}: P, I, O Amsterdam 4.6 4.7 5.9 Helsinki 2.7 3.0 5.0 NO_3^-: P, I, O Amsterdam 1.4 1.4 4.0 Helsinki 0.2 0.3 1.3	In both cities personal and indoor $PM_{2.5}$ were lower than highly correlated with outdoor concentrations. For most elements, personal and indoor concentrations were also highly correlated with outdoor concentrations.
Chillrud et al. (2004, 054799)	Personal: $PM_{2.5}$ Micro: $PM_{2.5}$ Home indoor and home outdoor Ambient: Urban fixed-site and upwind fixed site operated for three consecutive 48-h periods each week.	Elemental iron, manganese, and chromium are reported in this study out of 28 elements sampled.	Mean of duplicate samples: $PM_{2.5}$: 62 $\mu g/m^3$ Fe: 26 $\mu g/m^3$ Mn: 240 ng/m^3 Cr: 84 ng/m^3 Variability: 1-15%	Personal samples had significantly higher concentration of iron, manganese, and chromium than home indoor and ambient samples. The ratios of Fe (ng/ µg of $PM_{2.5}$) vs Mn (pg/ µg $PM_{2.5}$) showed personal samples to be twice the ratio for crustal material. Similarly for the Cr/Mn ratio. The ratios and strong correlations between pairs of elements suggested steel dust as the source. Time-activity data suggested subways as a source of the elevated personal metal levels.

Geyh et al. (2005, 186949)	Personal: TD, PM_{10}, $PM_{2.5}$ Micro: NR Ambient: TD, PM_{10}, $PM_{2.5}$	EC OC VOC also assessed	Mean (SD), units = $\mu g/m^3$: Summary Statistics by Area Location October 2001: Albany and West EC 5.9 (NA) OC 36 (NA) Liberty and Greenwich EC 5.3 (59) OC 30 (56) Park Place and Greenwich EC 14.5 (5.4) OC 72 (26) Church and Dey EC 7.9 (3.3) OC 48 (15) April 2002: Liberty and West EC 4.2 (2.1) OC 26 (13) Barclay and Greenwich EC 4.0 (2.6) OC 18 (14) Church and Dey EC 4.5 (1.9) OC 27 (15) Middle of the Pile EC 6.7 (1.0) OC 40 (25)	Comparison of recorded EC and OC values from October 2001 and April 2002 with previous studies suggests that the primary source of exposure to EC for the WTC truck drivers was emissions from their own vehicles.
Hanninen et al. (2004, 056812)	Personal: $PM_{2.5}$ Micro: NR Ambient: $PM_{2.5}$	$PM_{2.5}$ -bound S	Indoor Outdoor Athens 5.3 (2.0) 7.6 (5.1) Basel 2.6 (1.6) 3.3 (1.6) Helsinki 1.6 (1.3) 2.2 (1.5) Prague 3.1 (1.3) 4.0 (1.5)	Associated with indoor concentration: wooden building material, city, building age, floor of residence (i.e. ground, 1st, etc.), and use of stove other than electric.
Ho et al. (2004, 056804)	Personal: $PM_{2.5}$ Micro: NR Ambient: $PM_{2.5}$	OC EC OM TCA	Mean, Unit = $\mu g/m^3$ Indoors: OM = 18.1; TCA = 22.9 Outdoors: OM = 20.1; TCA = 26.5	The major source of indoor EC, OC, and $PM_{2.5}$ appears to be penetration of outdoor air, with a much greater attenuation in mechanically ventilated buildings.
Jacquemin et al. (2007, 192372)	Personal: $PM_{2.5}$ Micro: NA Ambient: $PM_{2.5}$	S	Mean, units = $\mu g/m^3$: Personal: 1.3 outdoor: 1.2	Authors suggest that "outdoor measurements of absorbance and sulphur can be used to estimate both the daily variation and levels of personal exposures also in Southern European countries, especially when exposure to ETS has been taken into account. For $PM_{2.5}$, indoor sources need to be carefully considered."
Jansen et al. (2005, 082236)	Personal, Micro, and Ambient: $PM_{2.5}$	Estimated Elemental Carbon (Abs) Elemental composition of a subset of personal, indoor and outdoor samples	Mean (SD), units = $\mu g/m^3$: Amsterdam, Helsinki P,O,P,O $PM_{2.5}$ 14.5, 15.7, 9.4, 11.4 Abs 1.4, 1.6, 1.3, 1.9 S 912.3, 1299.9, 605.3, 1435.7 Zn 13.2, 18.3, 11.7, 18.6 Fe 57.0, 71.3, 41.6, 79.2 K 87.4, 70.3, 103.1, 93.9 Ca 72.9, 40.2, 68.5, 36.4 Cu 5.4, 2.5, 4.3, 1.8 Si 29.7, 13.7, 79.5, 93.9 Cl 40.8, 72.7, 9.8, 44.2	For most elements, personal and indoor concentrations were lower than and highly correlated with outdoor concentrations. The highest correlations (median r.0.9) were found for sulfur and particle absorbance (EC), which both represent fine mode particles from outdoor origin. Low correlations were observed for elements that represent the coarser part of the $PM_{2.5}$ particles (Ca, Cu, Si, Cl).

Reference	Particle Sizes Measured	Component	Results	Primary Findings
Johannesson et al. (2007, 156614)	Personal, Micro, and Ambient: $PM_{2.5}$, PM_1	BS	$BS_{2.5}$ Mean SD Personal 0.65 0.47 Exclusively smokers 0.62 0.47 Residential indoor 0.56 0.47 Exclusively smokers 0.52 0.46 Residential outdoor 0.68 0.51 Exclusively smokers 0.71 0.54 Urban background 0.63 0.37 All measurements 0.68 0.40 PM_1/BS1 Personal 0.55 0.20 Residential indoor 0.54 0.45 Exclusively smokers 0.49 0.43 Residential outdoor 0.66 0.51 Exclusively smokers 0.68	Personal exposure of $PM_{2.5}$ correlated well with indoor levels, and the associations with residential outdoor and urban background concentrations were also acceptable. Statistically significantly higher personal exposure compared with residential outdoor levels of $PM_{2.5}$ was found for nonsmokers. PM_1 made up a considerable proportion (about 70–80%) of $PM_{2.5}$. For BS, significantly higher levels were found outdoors compared with indoors, and levels were higher outdoors during the fall than during spring. There were relatively low correlations between particle mass and BS. The urban background station provided a good estimate of the residential outdoor concentrations of both $PM_{2.5}$ and $BS_{2.5}$ within the city. The air mass origin affected the outdoor levels of both $PM_{2.5}$ and $BS_{2.5}$; however, no effect was seen on personal exposure or indoor levels.
Kim et al. (2005, 156640)	Personal: $PM_{2.5}$ Micro: NR Ambient: $PM_{2.5}$	SO_4^{2-}, EC, Ca^{2+}, Mn^{2+}, K, Na^+	Mean (SD), Units = $\mu g/m^3$: SO_4^{2-}: 2.7 (3.2) Ca^{2+}: 0.12 (0.12) Mg^{2+}: 0.02 (0.01) K: 0.07 (0.08) Na^+: 0.09 (0.20) EC: 0.60 (0.54)	Traffic-related combustion, regional, and local crustal materials were found to contribute 19% ± 17%, 52% ± 22%, and 10% ± 7%, respectively. Among participants that spent considerable time indoors, exposure to outdoor $PM_{2.5}$ includes a greater relative contribution from combustion sources, compared with outdoor (ambient) $PM_{2.5}$ measurements.
Koistinen et al. (2004, 156655)	Personal, Micro, and Ambient: $PM_{2.5}$	Black smoke, SO_4^{2-}, NO_3^-, NH_4^+, Al, Ca, Cl, Cu, K, Mg, P, S, Si, Zn	% contribution to $PM_{2.5}$ Outdoor - Indoor - Work - Personal CoPM * 35, 28, 32, 33 Secondary** 46, 36, 37, 31 Soil 16, 27, 27, 27 Detergents 0, 6, 2, 6 Sea Salt 3, 2, 1, 2 * CoPM is the difference between total mass and other identified components; i.e., primary combustion particles, nonvolatile primary and secondary organic particles, and particles from tire wear, water, etc. ** Secondary particles are the sum of sulfate, nitrate, and ammonium. 4 factors were identified for each exposure type (residential indoor, residential outdoor, workplace indoor, and personal). The factors contained the elements Al, Ca, Cl, Cu, K, Mg, P, S, Si, Zn, and black smoke. (insert in cell to left after consolidating PM size)	Population exposure assessment of $PM_{2.5}$, based on outdoor fixed-site monitoring, overestimates exposures to outdoor sources like traffic and long-range transport and does not account for the contribution of significant indoor sources.

Reference	Particle Sizes Measured	Component	Results	Primary Findings
Koutrakis et al. (2005, 095800)	Personal: $PM_{2.5}$ Micro: NR Ambient: $PM_{2.5}$	Elemental Carbon (EC), SO_4^{2-}	Mean (SD) data are provided for Baltimore and Boston, Units = $\mu g/m^3$: EC: (Baltimore, Boston) Winter: Seniors: NR, 1.4 (0.9) Children: 2.8 (1.8), 1.6 (1.6) COPD: 2.0 (1.2), NR SO_4^{2-}: (Baltimore, Boston) Winter: Seniors: 1.9 (1.1), 1.9 (1.2) Children: NR, 2.3 (1.7) COPD: 1.5 (0.8), NR Summer: Seniors: 5.7 (3.5), 2.9 (1.9)	Ambient $PM_{2.5}$ and SO_4^{2-} are strong predictors of respective personal exposures. Ambient SO_4^{2-} is a strong predictor of personal exposure to $PM_{2.5}$. Because $PM_{2.5}$ has substantial indoor sources and SO_4^{2-} does not, the investigators concluded that personal exposure to SO_4^{2-} accurately reflects exposure to ambient $PM_{2.5}$ and therefore the ambient component of personal exposure to $PM_{2.5}$ as well.
Kulkarni and Patil (2003, 156664)	Personal: PM_5 Micro: NR Ambient: PM_5	Pb Ni Cd Cu Cr Fe Mn	Personal samples, Units = $\mu g/m^3$: Mean ± SD Type Pb Occupational 4.384 ± 7.766 $\mu g/m^3$ Residential 4.093 ± 5.925 $\mu g/m^3$ 24-h integrated 4.205 ± 1.523 $\mu g/m^3$ Cd Occupational 0.201 ± 0.158 $\mu g/m^3$ Residential 0.111 ± 0.165 $\mu g/m^3$ 24-h integrated 0.134 ± 0.140 $\mu g/m^3$ Mn Occupational 1.979 ± 7.842 $\mu g/m^3$ Residential 0.180 ± 0.261 $\mu g/m^3$ 24-h integrated 1.983 ± 6.824 $\mu g/m^3$ K Occupational 3.473 ± 4.691 $\mu g/m^3$ Residential 4.589 ± 4.619 $\mu g/m^3$ 24-h integrated Check	All listed metals were detected in the ambient air where as only Lead, Cadmium, Manganese, and Potassium were detected in personal exposures. Mean daily exposure to lead exceeds the Indian NAAQS by a factor of 4.2. However, ambient concentration of lead conforms to this standard. There is a rising trend in the personal exposures and ambient levels of cadmium. However, they are low and do not pose any major health risk as yet. Personal exposures to toxic metals exceed the corresponding ambient levels by a large factor ranging from 6.1 to 13.2. Thus, ambient concentrations may underestimate health risk due to personal exposure of toxic metals. Outdoor exposure to toxic metals is greater than the indoor (ratios ranging from 2.3 to 1.1) except for potassium (ratio 0.77). However, there is no significant correlation between these two.

Geometric mean (GM) of personal and home indoor levels of $PM_{2.5}$, 14 elements, total VOC (TVOC) and 8 individual compounds were over 20% higher than their GM outdoor levels. Those of NO_2, 5 aromatic VOCs, and 5 other elements were close to their GM outdoor levels. For $PM_{2.5}$ and TVOC, personal exposures and residential indoor levels (in GM) were about 2 times higher among the tobacco-smoke exposed group compared to the non-smoke exposed group, suggesting that smoking is an important determinant ofthese exposures. Determinants for CO were visualised by real-time monitoring, and the authors showed that the peak levels of personal exposure to CO were associated with smoking, cooking and transportation activities. Moderate to good correlations were only found between the personal exposures and residential indoor levels for both $PM_{2.5}$ ($r = 0: 60$; $p < 0: 001$) and NO_2 ($r = 0: 47$; $p = 0: 003$).

Increases of 66–80% were found for these elements, which seem to be good wood-smoke markers. In addition, Cl, Mn, Cu, Rb, Pb, and BS were found to be possible wood-smoke markers, though not always to a statistically significant degree for personal exposure and indoor concentrations. For some of these elements, subgroups of wood burners had clearly higher levels which could not be explained by the information available. Sulfur, one of the more typical elements mentioned as a wood-smoke marker, showed no relation to wood smoke in this study due to the large variations in outdoor concentrations from LDT air pollution. This was also the case for $PM_{2.5}$ mass. Personal exposures and indoor levels correlated well among the subjects for all investigated species, and personal exposures were generally higher than indoor levels.

No other associations between exposure markers and biomarkers could be distinguished. ETS was not a predictor of any biomarker in the present study. The current study suggests that exposure to $PM_{2.5}$ at modest levels can induce oxidative DNA damage and that the association to oxidative DNA damage was confined to the personal exposure, whereas the ambient background concentrations showed no significant association. For most of the biomarkers and external exposure markers, significant differences between the seasons were found. Similarly, season was a significant predictor of SBs and PAH adducts, with avg outdoor temperature as an additional significant predictor.

Ambient: check component During non-burning times: 0.026 (0.030) During burning episodes: 0.010 (0.012)	Authors “found a significant between-subject variation between episodes and non-episodes in both the Exposure during agricultural burning estimates and subjects’ activity patterns. This suggests that the LG measurements at the central site may not always represent individual exposures to agricultural burning smoke “Evidence of “Hawthorne Effect”: During declared episodes (i.e. real and sham), subjects spent less time indoors at home and more time in transit or indoors away from home than during non-declared episode periods. The differences remained even when limited to weekdays only.

Reference	Particle Sizes Measured	Component	Results	Primary Findings
Zhao et al. (2007, 156182)	Personal, Micro, and Ambient: $PM_{2.5}$	EC, Cl, Si, NO_3	Units = $\mu g/m^3$: Personal: EC: 1.64 NO_3: 0.135 Si: 0.176 Cl: 0.116 Indoor: EC: 1.819 NO_3: 0.013 Si: 0.051 Cl: 0.024 Outdoor: EC: 1.876 NO_3: 0.292 Si: 0.115 Cl: 0.013	Four external sources and three internal sources were resolved in this study. Secondary NO_3^- and motor vehicle exhaust were two major outdoor $PM_{2.5}$ sources. Cooking was the largest contributor to the personal and indoor samples. Indoor environmental tobacco smoking also has an important impact on the composition of the personal exposure samples.

Table A-63. Summary of personal PM exposure source apportionment studies.

Reference	Study Design	Results	Primary Findings
Hopke et al. (2003, 095544)	Source apportionment of personal and indoor central and apartment and outdoor $_{PM2.5}$. Baltimore retirement home with 10 elderly subjects. July-Aug 1998.	% control P,I, C, O External Secondary SO_4^{2-} 46.3, 64.0, 79.0, 64.0 Unknown 13.6, 14.5, 17.4, 14.5 Soil 2.8, 3.1, 3.6, 3.1 Internal Gypsum 0.7, 0.4, 0.0, 0.0 Activity 36.2, 17.8, 0.0, 0.0 Personal care 0.4, 0.3, 0.0, 0.0	63% of personal exposure could be attributed to outdoor sources (with 46% from SO_4^{2-}), and resuspension of indoor PM during vacuuming, cleaning, or other activities contributed 36% of personal exposure.
Larson et al. (2004, 098145)	Source apportionment of personal and residences and central outdoor $PM_{2.5}$ around Seattle with 10 elderly subjects and 10 asthmatic children. The purpose of the article was to compare PMF2 and PMF3 methods. Seattle Sep 2000 and May 2001	PMF2: % control P,I,O Veg burn 28.8, 47.6, 56.7 Mobile 0.0, 3.6, 7.5 Fuel oil 0.0, 0.0, 6.7 S, Mn, Fe 8.1, 0.0, 0.0 Secondary 0.0, 34.5, 20.9 Cl-rich 9.9, 3.6, 3.7 Crustal 25.2, 10.7, 4.5 Crustal 2 27.9, 0.0, 0.0 PMF3: % control P,I, O Veg burn 41.0, 57.4, 71.3 Mobile 7.2, 4.3, 8.2 Secondary 19.3, 13.8, 18.0 Crustal 32.5, 24.,5 2.5	Results showed that vegetative burning was the largest contributor to personal exposure and that was related to outdoor combustion. Crustal exposures were related to indoor activities.
Zhao et al. (2006, 156181)	Source apportionment of personal and residential indoor and residential outdoor and central outdoor $PM_{2.5}$, Raleigh and Chapel Hill NC with 38 subjects. Summer 2000 and Spring 2001.	% control P, I, R,O Motor vehicle 10.0, 9.4, 17.2, 19.4 Soil 3.5, 3.7, 9.3, 8.5 Secondary SO_4^{2-} 15.9, 22.5, 59.3, 61.9 Secondary NO_3^- 4.4, 4.7, 7.6, 7.8 ETS 7.0, 10.0, 0.0, 0.0 Personal care and activity 8.0, 19.1, 0.0, 0.0 CU-factor mix with indoor soil 0.4, 1.2, 0.0, 0.0 Cooking 52.5, 53.6, 0.0, 0.0	Secondary sulfate was the largest ambient source and the largest ambient contribution to personal exposure. Cooking produced the largest contribution to personal and indoor concentrations. Note that sums over 100% because multiple sources obscured PMF resolution.

Reference	Study Design	Results	Primary Findings
Meng et al. (2007, 194618)	Source apportioned infiltration for personal and residential indoor and residential outdoor and central outdoor $_{PM2.5}$. Los Angeles, Houston, and Elizabeth, NJ with 100 non-smoking residences and residents in each city. In each season between summer 1999 and spring 2001 (RIOPA).	% contr Outdoor Indoor (Outdoor Origin) Mechanically generated 2, 17 Primary Combustion 43, 43 Secondary Formation* 55, 40 *excludes nitrates	Differential infiltration of the $PM_{2.5}$ resulted in a reduction of secondary formation products relative to outdoors.
Reff et al. (2007, 156045)	Functional group distinction for personal and residential indoor and residential outdoor and central outdoor $PM_{2.5}$, $PM_{2.5}$ samples from 219 homes were used for this analysis. Los Angeles, Houston, and Elizabeth, NJ with 100 non-smoking residences and residents in each city. In each season between summer 1999 and spring 2001 (RIOPA).	SO_4^{2-}: R, O, I, P O 1.0 I 0.54-0.76 1.0 P 0.54-0.73 0.84-0.90 1.0 C = O: R, O, I, P O 1.0 I 0.12-0.61 1.0 P -0.13-0.69 0.07-0.77 1.0 CH: R, O, I, P O 1.0 I -0.08-0.35 1.0 P -0.07-0.19 0.41-0.85 1.0	The main finding was that indoor and personal levels of CH in organic carbons were found to be substantially higher than outdoors. This reduced the polarity of indoor and personal organic carbons
Zhao et al. (2007, 156182)	Source apportionment of personal and indoor school and outdoor school $PM_{2.5}$. Denver with 56 asthmatic children. Oct 2002-March 2003 and Oct 2003-March 2004.	% contr P IO Secondary SO_4^{2-} 4.3 8.9 9.6 Soil 6.6 4.2 12.4 Secondary NO_3^- 9.4 2.8 40.8 Motor vehicle 13.3 26.5 26.5 Cl-based cleaning 2.8 0.4 0.0 Cooking 54.8 30.2 0.0 ETS 9.2 2.1 0.0	The largest personal exposure was from cooking (54.8%), but motor vehicle emissions were the largest outdoor contributor (13.3%) to personal exposure. Secondary nitrate comprised the largest outdoor source but accounted for only 9.4% of personal exposure.
Strand et al. (2006, 089203)	Using positive matrix factorization and an extrapolation method to estimate $PM_{2.5}$ based on SO_4^{2-}Fe components. Denver. Winter 1999-2000 and 2000-2001.	Estimation method, Mean (SD, range): PMF: 7.42 (1.93, 3.43-12.89) Extrapolation Method: Using SO_4^{2-}: 6.38 (1.60, 3.20-10.97) Using SO_4^{2-} and Fe: 6.50 (1.36, 3.54-10.12) Using SO_4^{2-} and Fe, temperature adjusted: 7.02 (1.48, 3.79-11.02) Using SO_4^{2-} (no gamma): 8.23 (2.06, 4.12-14.14)	Similar results were found with each technique.

Cortez-Lugo et al. (2008, 156368)	Objective: To determine personal $PM_{2.5}$ and its relationship with outdoor and indoor $PM_{2.5}$ and PM_{10}. Methods: Linear regression model used to compare personal and indoor $PM_{2.5}$. I/O variation studied using analysis of variance and predictors determined by generalized estimating equation models. I/O $PM_{2.5}$ ratio transformed into natural logarithm. Subjects: 38 nonsmoking long-time Mexico residents with COPD. Mexico City, Mexico. Feb-Nov 2000.	N/A	$PM_{2.5}$: Average: 1.2 Range: 0.05-6.1
Diapouli et al. (2008, 190893)	Objective: To characterize the PM_{10f} $PM_{2.5}$, UFP concentrations at primary schools. To examine the relationship between indoor and outdoor concentrations. Methods: Chemical analysis of collected filters. Regressions to examine correlations between indoor and outdoor concentrations. Subjects: 7 primary schools with different characterizations of urbanization and traffic density in Athens, Greece. No ventilation system. Nov. 2003-Feb. 2004 and Oct.-Dec. 2004.	N/A	PM_{10}: 0.54-2.46 $PM_{2.5}$- 0.67-2.77 UFP- 0.33-0.74
Dimitroulopoulou et al. (2006, 090302)	Objective: To develop a probabilistic indoor air model (INDAIR). Methods: INDAIR predicts frequency distributions of concentrations of up to 4 pollutants simultaneously (NO_2, CO, PM_{10}, $PM_{2.5}$). 3 scenarios: no source, gas cooking, smoking. Subjects: 5 UK sites- Harwell (rural), Birmingham East (urban background), Bradford (urban center), Bloomsbury (urban center), Marylebone Road (roadside). Winter (October 1-March 31), summer (April 1-September 30), 1997-1999.	N/A	No source: PM_{10}: 0.5-0.65; $PM_{2.5}$: 0.6-0.7 Gas cooking: PM_{10}: 0.6-0.9 (bedroom), 1.0-2.0 (lounge), 1.6-4.3 (kitchen); $PM_{2.5}$: 0.74-0.9 (bedroom), 0.9-1.6 (lounge), 1.6-2.9 (kitchen) Smoking: PM_{10}: 0.7-1.1 (bedroom), 1.1-2.7 (lounge), 1.1-2.5 (kitchen); $PM_{2.5}$: 0.8-1.3 (bedroom), 1.3-2.8 (lounge), 1.4-2.6 (kitchen)
Fromme et al. (2008, 155147)	Objective: To characterize the chemical and morphological properties of PM in classrooms and in corresponding outdoor air. Methods: PM F_{inf} derived from sulfate Finf and a correction factor that results from division of BPM (increase of indoor PM per outdoor PM, linear relationship) by B^{sulf} (increase of indoor sulfate per outdoor sulfate, linear relationship). If no indoor source, the sulfate F_{inf} is equal to the sulfate I/O. Subjects: Primary school in northern Munich. Densely populated residential area 160m away from a very busy street. Classrooms had 21-23 students. Sampling during teaching hours. Oct.-Nov. 2005.	N/A	PM_{10}: SO_4^{2-}: 0.3, NO_3^-: 0.1, Cl^-: 0.6, Na^{2+}: 0.9, NH_4^+: 0.1, Mg: 0.6, Ca^{2+}: 1.4, EC: 0.7, OC: 1.1 $PM_{2.5}$: SO_4^{2-}: 0.4, NO_3^-: 0.2, Cl^-: 0.5, Na^{2+}: 0.6, NH_4^+: 0.3, Mg: 0.5, Ca^{2+}: 1.6

Martuzevicius et al. (2008, 190886)	Objective: To determine the contribution of traffic-related PM to the indoor aerosols. Methods: Receptor modeling based on a PARAFAC model. Subjects: 6 houses 30-300m from a highway, with conventional windows, central HVAC, and with smoking and cooking allowed. Spring: Mar. 30-May 14, 2004. Fall: Sept. 13-Oct. 22, 2004. Cincinnati, OH.	N/A	Range- $PM_{2.5}$: Spring: 0.5 ± 0.2-2.9 ± 1.2; Fall: 0.7 ± 0.1-4.7 ± 6.9 EC: Spring: 0.3 ± 0.1-2.2 ± 1.7; Winter: 0.6 ± 0.1-1.3 ± 0.7 OC: Spring: 1.0 ± 0.7-6.9 ± 3.9; Winter: 1.2 ± 0.1-7.6 ± 10 Si: Spring: 0.4 ± 0.1-5.1 ± 3.9; Winter: 0.5 ± 0.1-5.3 ± 4.5 S: Spring: 0.4 ± 0.1-0.7 ± 0.1; Winter: 0.5 ± 0.1-0.9 ± 0.4 Mn: Spring: 0.3 ± 0.2-0.8 ± 0.6; Winter: 0.3 ± 0.2-1.0 ± 0.2 Fe: Spring: 0.3 ± 0.0-1.3 ± 0.8; Winter: 0.4 ± 0.1-0.9 ± 0.6 Zn: Spring: 0.3 ± 0.1-0.7 ± 0.6; Winter: 0.6 ± 0.1-1.1 ± 0.8 Br: Spring: 0.3 ± 0.1-1.0 ± 0.5; Winter: 0.2 ± 0.1-0.9 ± 0.6 Pb: Spring: 0.3 ± 0.3-0.9 ± 0.6; Winter: 0.2 ± 0.2-1.9 ± 2.3
Meng et al. (2005, 058595)	Objective: Analyses of RIOPA data, which investigated relationships between indoor, outdoor, and personal exposure for several air pollutants. Methods: PM measured on Teflon filters collected by PEMs for 48h. The mass balance model and RCS statistical model used to estimate indoor and and personal PM concentrations. Subjects: 212 nonsmoking homes sampled. Houston, TX; Los Angeles County, CA; Elizabeth, NJ. Summer 1999-spring 2001, all 4 seasons.	$PM_{2.5}$- 0.46	Los Angeles: $PM_{2.5}$: Mean: 0.84, Median: 0.90; EC: Mean: 0.93, Median: 0.92; OC: Mean: 1.32, Median: 1.31 Elizabeth: $PM_{2.5}$: Mean: 0.99, Median: 0.86; EC: Mean: 1.0, Median: 0.85; OC: Mean: 2.4, Median: 1.8 Houston: $PM_{2.5}$: Mean: 1.16, Median: 1.02; EC: Mean: 1.0, Median: 0.71; OC: Mean: 2.25, Median: 2.35
Molnár et al. (2007, 156774)	Objective: To characterize and compare indoor and outdoor $PM_{2.5}$ trace element concentrations in difference microenvironments related to children. Methods: Elemental concentrations analyzed using X-ray fluorescence spectroscopy. Subjects: 40 sampling sites (10 classrooms in 5 schools, 10 preschools, 20 non-smoking homes). 3 communities in Stockholm, Sweden. Sampled once during spring and once during winter. Dec. 1, 2003-July 1, 2004.	$PM_{2.5}$ (containing S or Pb): 0.4-0.9	S (median): Both seasons: 0.61 (homes), 0.53 (schools), 0.69 (preschools); Winter: 0.47 (homes), 0.36 (schools), 0.63 (preschools); Spring: 0.63 (homes), 0.55 (schools), 0.90 (preschools) Pb (median): Both seasons: 0.70 (homes), 0.59 (schools), 0.70 (preschools); Winter: 0.62 (homes), 0.43 (schools), 0.63 (preschools); Spring: 0.70 (homes), 0.64 (schools), 0.75 (preschools)

Ng et al. (2005, 155996)	Objective: To estimate PM exposures following the September 11, 2001 attack in NYC. Methods: Outdoor $PM_{2.5}$ interpolated and used in a deterministic micro-environmental model (INTAIR) to simulate analytically concentrations in indoor micro-environments. Linear regression equations used. Subjects: Lower Manhattan residents divided into representative individuals – home-maker, office/shop-worker, student/child. Estimates Sept. 14-31.	N/A	Mean I/O in home simulated with INTAIR: No Source: 0.6 Smoking: 1.9 Cooking: 1.3 Smoking and Cooking: 2.3 I/O of micro-environments simulated by analytical and empirical methods (no indoor source) : Office/Shop: 0.4 Classroom: 0.9: Transport Area: 1.9 Store: 1.2
Paschold et al. (2003, 156847)	Objective: To identify PM sources inside homes with evaporative coolers. Methods: PM element composition analysis by ICP-MS. Subjects: 10 residences. El Paso, TX. Summer 2001.	N/A	PM_{10}: Na: 0.33, Mg: 0.43, Al: 0.50, K: 0.48, Ca: 0.40, Ti: 0.52, Mn: 0.48, Fe: 0.46, Cu: 0.74, Zn: 0.52, Ba: 0.54, Pb: 0.76 $PM_{2.5}$: Na: 0.20, Mg: 0.29, Al: 0.34, K:0.30, Ca: 0.52, Ti: 0.40, Mn: 0.35, Fe: 0.30, Cu: 0.67, Zn: 0.34, Ba: 0.47, Pb: 0.51
Polidori et al. (2007, 156877)	Objective: To investigate the relationships of indoor and outdoor $PM_{2.5}$, its components, seasonal variations, and gaseous copollutants. Methods: F_{inf} estimated by analysis of I/O's and a recursive model technique. Subjects: 2 retirement facilities in Los Angeles, CA. July 6-Aug. 20, 2005. Aug. 24-Oct. 15, 2005. Oct. 19-Dec. 10, 2005. Jan. 4-Feb. 18, 2006.	$PM_{2.5}$: July 6-Aug. 20: 0.71 ± 0.10; Aug. 24-Oct. 15: 0.60 ± 0.05; Oct. 19-Dec. 10: 0.59 ± 0.07; Jan. 4-Feb. 18: 0.45 ± 0.06 OC: July 6-Aug. 20: 0.86 ± 0.05; Aug. 24-Oct. 15: 0.77 ± 0.09; Oct. 19-Dec. 10: 0.82 ± 0.07; Jan. 4-Feb. 18: 0.64 ± 0.10 EC: July 6-Aug. 20: 0.73 ± 0.07; Aug. 24-Oct. 15: 0.71 ± 0.05; Oct. 19-Dec. 10: 0.77 ± 0.06; Jan. 4-Feb. 18: 0.64 ± 0.10	Only I/O's ≤1considered
Ramachandran et al. (2003, 195017)	Objective: To examine variability in measurements of 24h avg and 15min avg $PM_{2.5}$ concentrations. Methods: Linear regression of gravimetric measurements. Subjects: 3 urban residential neighborhoods in Minneaopolis-St. Paul, MN. 9-10 nonsmoking residences. Spring (April 26-June 2), summer (June 20-Aug. 10), fall (Sept. 23-Nov. 20) of 1999.	N/A	24h avg: Mean: 1.7, Median: 1.3, Standard deviation: 1.6 15min avg: Mean: 2.7, Median: 1.2, Standard deviation: 8.7
Rojas-Bracho et al. (2004, 054772)	Objective: To examine determinants of personal exposure to $PM_{2.5}$, PM_{10}, $PM_{2.5-10}$. Methods: 2 sets of mixed models. Personal exposures modeled as dependent variables. Subject variability modeled using random effects. Explanatory variables and season modeled as fixed effects. Subjects: 18 COPD subjects in nonsmoking households. Boston, MA. Winters of 1996 and 1997, summer of 1996.	N/A	$PM_{2.5}$: Winter: Mean: 1.58, Median: 2.11; Summer: Mean: 1.08, Median: 0.88 PM_{10}: Winter: Mean: 2.02, Median: 3.77; Summer: Mean: 1.14, Median: 1.05 $PM_{2.5-10}$: Winter: Mean: 2.65, Median: 3.59; Summer: Mean: 1.26, Median: 1.39

Reference	Study Design	F_{inf}	I/O
Sarnat et al. (2006, 089166)	Objective: To assess the ability of outdoor $PM_{2.5}$ its volatile and nonvolatile components and particle sizes to infiltrate indoors. Methods: $PM_{2.5}$ mass contributions estimated by the mean concentration ratio between each component and $PM_{2.5}$. Indoor and outdoor particle concentrations relationships examined by Spearman correlation coefficient. I/O concentration ratios used during overnight (nonsource) period to estimate fraction of ambient particles remaining airborne indoors (F_{inf}). Subjects: 17 occupied, nonsmoking Los Angeles, CA residences. July 28, 2001-Feb. 25, 2002.	$PM_{2.5}$: Median: 0.48, Interquartile range: 0.39-0.57 BC: Median: 0.84, Interquartile range: 0.70-0.96 UFP (0.02-0.03 µm): Median: 0.50, Interquartile range: 0.39-0.60 UFP (0.08-0.3 µm): Median: ~0.75 Coarse particles (5-10 µm): Median: <0.17	$PM_{2.5}$: Overnight: 0.40-0.57, Morning: 0.43-0.74, Afternoon: 0.45-0.90, Evening: 0.42-0.82 BC: Overnight: 0.70-0.97, Morning: 0.67-0.98, Afternoon: 0.77-1.04, Evening: 0.70-1.01
Stranger et al. (2008, 190884)	Objective: To assess indoor air quality by determining indoor and outdoor $PM_{2.5}$ mass concentrations, elemental composition, and gaseous compounds. Methods: PM mass concentrations determined gravimetrically. Subjects: 27 primary schools in city center and suburbs of Antwerp, Belgium. Dec. 2002 and June 2003.	N/A	$PM_{2.5}$: Urban: Range: 0.3-6.9, Average: 1.3; Suburban: Range: 0.2-8.8, Average: 2.3 V, Ni, Zn, Pb, Br, Mn: <1 Cl, Ca, Al, Si, K, Ti, Fe: >1 BS: Urban: Average: Dec.- 0.7 ± 0.1, June- 1.1 ± 0.3; Suburban: Dec.- 0.8 ± 0.2, June-1.0 ± 0.4
Stranger et al. (2009, 190883)	Objective: To assess indoor air quality in residences by quantifying various gaseous pollutants, and PM mass concentrations, elemental composition, and water-soluble ionic content. Methods: PM mass concentrations gravimetrically determined. Elemental bulk analysis on filters. Subjects: 19 residential homes in Antwerp, Belgium that were a subset of participants in the ECRHS II study.	N/A	PM_1: Houses 1-15: Average: 2.0, Range: 0.3-9.6; Smokers: Average: 3.9, Range: 1.2-9.7; Non-smokers: Average: 0.8, Range: 0.3-14 $PM_{2.5}$: Houses 1-15: Average: 1.5, Range: 0.4-5.4, Smokers average: 2.5, Smokers range: 1.2-5.4, Non-smokers average: 0.8, Non-smokers range: 0.4-1.3; Houses 16-19: Average: 2.6, Range: 0.3-3.9 PM_{10}: Houses 1-15: Average: 1.3, Range: 0.4-4.1, Smokers average: 2.1, Smokers range: 1.1-4.1, Non-smokers average: 0.8, Non-smokers range: 0.4-1.2 Ca, Ti, V, Cr, Mn, Fe, Ni, Zn, Pb, Si, S, Cl: <1 K, Cu, Br, Al: >1
Turpin et al. (2007, 157062)	Objective: To characterize and compare outdoor, indoor, personal $PM_{2.5}$ exposure. Identify indoor and personal $PM_{2.5}$ sources. Estimate outdoor $PM_{2.5}$ effect on indoor and personal $PM_{2.5}$. RIOPA study. Methods: F_{inf} calculated in three ways: RCS model used to obtain constant F_{inf}. Mass balance model shows F_{inf} varying with AER. Robust regression uses major $PM_{2.5}$ species for home-specific F_{inf}. Subjects: 309 nonsmoking adults and 118 children with no preexisting conditions. 219 homes sampled. Elizabeth NJ, Houston TX, and Los Angeles County CA.	$PM_{2.5}$: RCS model: 0.46 Least-Trimmed Squared Regression: Mean: 0.69, Median: 0.70, SD: 0.23 Mass Balance Model: ~0.08-~0.85	Los Angeles: $PM_{2.5}$: Mean: 0.84, Median: 0.90 EC: Mean: 0.93, Median: 0.92 OC: Mean: 1.32, Median: 1.31 Elizabeth: $PM_{2.5}$: Mean: 0.99, Median: 0.86 EC: Mean: 1.0, Median: 0.85 OC: Mean: 2.4, Median: 1.8 Houston: $PM_{2.5}$: Mean: 1.16, Median: 1.02 EC: Mean: 1.0, Median: 0.71 OC: Mean: 2.25, Median: 2.35

Wallace and Williams (2005, 057485)	Objective: To estimate the contribution of outdoor $PM_{2.5}$ to personal exposure in high-risk subpopulations. Methods: Longitudinal regressions of estimated indoor and outdoor $PM_{2.5}$ for F_{inf}. Subjects: 29 African-Americans with hypertension and 8 with implanted cardiac defibrillators. Measured 7d/season, 4 seasons in 2000-2001. Raleigh, NC.	Range: 0.35-0.87	$PM_{2.5}$: Mean: 1.08 ± 1.05, Median: 0.75, Range: 0.24-9.48 S: Mean: 0.59 ± 0.16, Median: 0.58, Range: 0.17-1.06
Williams et al. (2003, 053338)	Objective: To estimate ambient $PM_{2.5}$ contributions to personal and indoor residential PM mass concentrations. Methods: F_{inf} estimated from least squares, regression analysis, and mixed model slope. Subjects: Nonsmoking, ambulatory, ≥ 50yrs. 2 cohorts: mostly Caucasian with implanted cardiac defibrillators in Chapel, NC; 30 African-Americans with controlled hypertension in low-to-moderate SES neighborhoods in Raleigh, NC. 7d/season, 4 seasons in 2000-2001.	Least squares estimate of indoor filtration factors: Mean: 0.42 ± 0.38, Range: -0.55 to 1.62 Regression analysis: 0.43 ± 0.06 Mixed model slope: Mean- 0.45 ± 0.21, Range- 0.05-0.94	N/A
Williams et al. (2008, 191201)	Objective: To examine the spatial variability of $PM_{2.5}$ and $PM_{10-2.5}$ and their components to determine the suitability of conducting health outcome studies using a central site monitor in a metropolitan area having multiple source impacts. Methods: Gravimetric analysis of PM mass concentrations. ED-XRF analysis of PM elements. Subjects: Non-smoking, ambulatory, and living in detached homes and non-smoking households. Detroit, MI.	$PM_{2.5}$: Range: 0.16-6.45, Mean: 0.7 ± 0.33, Median: 0.70 (indicate indoor sulfur source when F_{inf}>1)	N/A
Wilson and Brauer (2006, 088933)	Objective: To provide additional insight into factors affecting exposure to airborne PM and the resultant health effects. Methods: F_{inf} estimated by mass balance equation. Subjects: 16 nonsmoking subjects with COPD. 54-86yrs. Vancouver, British Columbia. April-Sept. 1998.	SO_4^{2-}: 0.72	N/A
Wu et al. (2006, 179950)	Objective: To assess personal $PM_{2.5}$ exposures from ambient sources and agriculture burning smoke. Methods: F_{inf} estimated by RCS model. Application of Robust regression algorithm. Subjects: 33 adult asthmatics. 18-52yrs. Pullman, WA. Sept. 3, 2002-Nov. 1, 2002.	Range: 0.25-0.94	N/A

Reference	Study Design	F_{inf}	I/O
Yang et al. (2009, 190885)	Objective: To characterize the concentrations of different indoor air pollutants. Methods: PM_{10} collected on pall flex membrane filer using MiniVol portable air samplers. Arithmetic and geometric means calculated for indoor concentrations. Differences in concentrations measured by Kruskal-Wallis test. Subjects: 55 schools in 6 metropolitan areas in Korea. Samples from a classroom, laboratory, and computer classroom. 3 seasons, July-Dec. 2004.	N/A	PM_{10}: Classroom: Summer: 1.98, Autumn: 2.25, Winter: 2.07, Total: 2.06 Laboratory: Summer: 1.33, Autumn: 1.32, Winter: 1.72, Total: 1.46 Computer classroom: Summer- 0.77, Autumn: 1.43, Winter: 2.08, Total: 1.43
Zhu et al. (2005, 190081)	Objective: To determine penetration behavior of outdoor ultrafine particles into indoor environments in areas close to freeways. Methods: Dynamic mass balance model. Subjects: 4 2-bedroom apartments within 60m from the center of the 405 Freeway in Los Angeles, CA. Non-smoking tenants. 2 sampling periods (non-cooking, non-cleaning): Oct.-Dec. 2003 and Dec. 2003-Jan. 2004.	N/A	Highest (largest ultrafine particles-70-100nm): 0.6-0.9 Lowest (smallest ultrafine particles-10-20nm): 0.1-0.4

1. I/O estimated from Figure 8 in study.
2. I/O calculated from indoor and outdoor concentrations in Table 1 in study.
3. F_{inf} measured by coefficient of determination, R^2.
4. RIOPA calculated I/O's.
5. I/O calculated from mean and median indoor and outdoor concentrations listed in Table 1 of study.
6. I/O's estimated from Figure 3 in study.
7. Mean and median I/O concentrations calculated from all residences in study.
8. F_{inf} estimated from Figure 2 in study.
9. F_{inf} presented in box plot (Figure 8), however data is difficult to deduce. No numeric values reported.

Table A-65. Summary of PM – copollutant exposure studies.

<table>
<tr><th>Reference</th><th>PM metric</th><th>Copollutant metric</th><th>Association between PM and copollutant</th><th>Primary findings</th></tr>

Reference	PM metric	Copollutant metric	Association between PM and copollutant	Primary findings
Ito et al. (2007, 156594)	Ambient $PM_{2.5}$	Ambient O_3, NO_2, SO_2, CO	Shown in figure format only.	Authors tested relationship between meteorological variables and copollutants to determine if multi-pollutant models are impacted by spatial or temporal variation or by meteorological conditions. Multicollinearity varied by pollutant and season.
Kaur et al. (2005, 086504)	Fixed-site and personal $PM_{2.5}$, personal UFP	Fixed site and personal CO	Personal R: $PM_{2.5}$ UFPCO $PM_{2.5}$ 1 0.5 0.2 UFP 0.5 1 0.7 CO 0.2 0.7 1	Fairly low correlation was observed between $PM_{2.5}$ and CO and between $PM_{2.5}$ and UFP, stronger correlations between UFP and CO.
Kaur et al. (2005, 088175)	Fixed-site and personal $PM_{2.5}$ analyzed post-sample for light absorbance (as indicator for carbonaceous aerosol), personal UFP	Fixed site and personal CO	Personal R: R $PM_{2.5}$ Abs CO UFP $PM_{2.5}$ 1 0.3 -0.1 0.0 Abs 0.3 1 0.2 0.7 CO -0.1 0.2 1 0.1 UFP 0.0 0.7 0.1 1	Strongest correlation observed between UFP and absorption, which is reasonable given that much absorptive carbonaceous aerosol is in the ultrafine range.
Sørenson et al. (2005, 089428)	Personal, indoor residential, and outdoor residential $PM_{2.5}$ and BC	Personal, indoor residential, and outdoor residential NO_2	Personal exposure regression coefficients to: | | $PM_{2.5}$ | BC | NO_2 | | --- | --- | --- | --- | | Bedroom | 0.72 | 0.47 | 0.70 | | Front door | 0.46 | 0.61 | 0.60 | | Background | 0.29 | 0.03 | 0.56 |	Personal NO_2 concentration is more strongly influenced by background than $PM_{2.5}$ or BC.
Sabin et al. (2005, 087728)	BC, particle-bound PAH on a school bus.	NO_2 on a school bus.	| | BC | PB-PAH | NO_2 | | --- | --- | --- | --- | | BC | 1 | 0.94 | 0.49 | | PB-PAH | | 1 | 0.37 | | NO_2 | | | 1 | Note that these correlations are computed from data presented by Sabin et al. for mean concentrations when the test bus travelled behind different vehicles.	Less correlation was observed between NO_2 and PM species. This study was aimed more at fuel choices and control technologies for children's exposures on school buses.
Lai et al. (2004, 056811)	Microenvironmental and personal $PM_{2.5}$ and trace elements for personal exposure (P), residential indoor (RI), residential outdoor (RO), and workplace (WI) measurements.	Microenvironmental and personal VOCs, NO_2, and CO.	| R ($PM_{2.5}$) | P | RI | RO | WI | | --- | --- | --- | --- | --- | | TVOC | 0.21 | 0.21 | 0.41 | -0.32 | | NO_2 | -0.1 | -0.02 | -0.16 | 0.09 | | CO | -0.07 | NR | NR | NR |	The EXPOLIS Oxford study was more focused on the indoor-outdoor exposure relationship, but the correlation results showed no important relationships between the pollutants shown.
Gomez-Perales et al. (2004, 054418; 2007, 138816)	Microenvironmental $PM_{2.5}$ with SO_4^{2-}, NO_3-, EC, OC.	Microenvironmental CO.	Ratio of Conc $PM_{2.5}$ CO Benzene Minibus/Bus 1.04 1.54 2.01 1.20 1.40 1.33 Minibus/Metro 1.70 2.02 3.20 1.43 3.03 3.10	Morning and evening measurements of $PM_{2.5}$ were on avg higher and more variable than for benzene and CO (in order). Benzene and CO had higher and more variable concentrations for minibuses than for buses and metros, respectively, while $PM_{2.5}$ concentrations were not substantially different for buses and minibuses.

Reference	PM metric	Copollutant metric	Association between PM and copollutant	Primary findings
Sarnat et al. (2001, 019401)	Fixed site and personal $PM_{2.5}$ monitors.	Ambient O_3, NO_2, SO_2, and CO	R: $PM_{2.5}$ 1; O_3 0.67; NO_2 0.37; SO_2 ---; CO 0.15 $PM_{2.5}$: O_3 -0.72; NO_2 0.75; SO_2 -0.17; CO 0.69 O_3: NO_2 -0.71; SO_2 0.41; CO -0.67 NO_2: SO_2 -0.17; CO 0.76 SO_2: CO -0.12 CO: 1	Strong association between ambient NO_2 and personal $PM_{2.5}$ suggests that ambient gas may be a suitable surrogate for personal exposure.

Annex B. Dosimetry

B.1. Ultrafine Disposition

Table B-1. Ultrafine disposition in humans.

Reference	Study Group	Aerosol	Study Protocol	Observations
Mills et al.(2006, 088770)	Healthy nonsmokers (5 M, 5 F; 21-24 yr)	Carbon - 99mTc 108 nm CMD (σg = 2.2) Technegas Generator	Lung activity in the lung was measured at 0, 1, and 6 h post aerosol inhalation.	On avg, lung activity decreased 3.2 ± 0.7% during the first h and 1.2 ± 1.7% over the next 5 h. With 95.6% of the particles in the lungs at 6 h post inhalation and no accumulation of radioactivity detected over the liver or spleen, findings did not support rapid translocation from the lungs into systemic circulation.
Möller et al. (2008)	Healthy nonsmokers (n = 9; 50 ± 11 yr) Smokers (n = 10; 51 ± 10 yr) COPD patients (n = 7; 69 ± 10 yr)	Carbon - 99mTc ~100 nm CMD Technegas Generator	On two separate occasions, subjects inhaled 100 mL aerosol boli to target front depths of 150 and 800 mL into the lungs to target the airways and alveoli, respectively. Retention measured at 10 min, 1.5, 5.5, 24 and 48 h post inhalation. Isotope (99mTc) leaching from particles assessed via filters in saline, blood, and urine. 81mKr utilized to assess ventilation.	Shallow airways boli-Total deposition in airways (shallow boli) similar between groups. Pattern of deposition was significantly more central in the healthy subjects which was thought due to non-uniform ventilation distribution in smokers and COPD patients as visualized by gamma-camera scans. Airway retention after 1.5 h was significantly lower in healthy subjects (89 ± 6%) than smokers (97 ± 3%) or COPD patients (96 ± 6%). At 24 and 48 h, retention significantly remained higher in COPD patients (86 ± 6% and 82 ± 6%) than healthy subjects (75 ± 10% and 70 ± 9%). Deep alveolar boli - Total deposition in alveoli (deep boli) significantly greater in smokers (64 ± 11%) and COPD patients (62 ± 5%) than healthy subjects (50 ± 8%). Alveolar retention of particles similar at all times between groups. For example, at 48 h, 97 ± 3% in healthy subject, 96 ± 3% in smokers, and 96 ± 2% in COPD patients. Retention at 24 and 48 correlated with isotope leaching, suggesting that the small amount of clearance primarily reflected the disassociation of 99mTc from the particles with little transport of particles from the lungs.
Wiebert et al. (2006, 156154)	Subjects having varied health status (9M, 6F; 46-74 yr) 6 healthy 5 asthmatic 4 smokers	Carbon - 99mTc 87 nm CMD (σg = 1.7) Technegas Generator	Technegas system was modified to reduce leaching of 99mTc radiolabel from particles. The avg tidal volume during aerosol inhalation was 1.8 L (range 0.8-3.3). Activity in chest region measured at 0, 2, 24, 46, and 70 h after inhalation. Leaching assessed in vitro and via urine collection.	Lung function not significantly different between healthy and affected lungs. The aerosol deposition fraction was 41 ± 10%. Lung retention was 99 ± 3%, 99 ± 5%, and 99 ± 10% at 24, 46, and 70 h post inhalation. Cumulative in vitro leaching by 70 h was 2.6 ± 0.96%. Except for radiotracer leaching from particles (1.0 ± 0.6% of initially deposited activity in urine by 24 h), there was not significant clearance from the lungs by 70 h. Individual leaching was not correlated with individual retention.
Wiebert et al. (2006, 157146)	Healthy subjects (4M, 5F; 56 ± 9 yr) Asthmatics (2M, 3F; 59 ± 6 yr) Control (1M; 50 yr)	Carbon - 99mTc 34 nm CMD (σg = 1.5) Technegas Generator	Slow deep aerosol inhalations with 10 s breath hold. Mean inhalation time of 6 min. Control subject inhaled aerosol with loosely bound radiolabel. Retention scans at 10 min, 60 min, 100 min, and 24 h post inhalation. Leaching assessed in vitro and via collection of blood and urine.	Avg deposition fraction of 60 ± 17% which was correlated with tidal volume during aerosol inhalation (p = 0.01). Activity excreted in urine over 24-h post inhalation was 51% in the control subject (high 99mTc disassociation) and 3.6 ± 0.9% of deposited activity. In the blood of the control subject, activity was 30%, 31%, and 5% of the deposited activity at 20 min, 80 min, and 24-h (respectively), whereas it was only 0.9 ± 0.6%, 1.1 ± 0.4%, and 1.5 ± 0.5% the other 13 subjects at these times. Lung retention in the control subject was 30% at 1-h and 18% at 24 h. In the remainder of subjects, lung retention was approximately 100% through 24 h.

HERO is a database of scientific literature used by U.S. EPA in the process of developing science assessments such as the Integrated Science Assessments (ISA) and the Integrated Risk Information System (IRIS).

Table B- 2. Ultrafine disposition in animals.

Reference	Study Group	Aerosol	Study Protocol	Observations
Bermudez et al.(2004, 056707)	Fischer 344 rats, females (6 wk) B3C3F1 mice, females (6 wk) Hamsters, females (6 wk)	TiO_2: 1.29-1.44 µm MMAD (σg = 2.46-3.65), 21 nm primary particles	Animals exposed 6 h/day, 5 day/wk, for 13 wk to 0.5, 2 and 10 mg/m^3. Control animals exposed to filtered air. Animals sacrificed at 0, 4, 13, 26, and 56 (49 for hamsters) post-exposure. Groups of 25 animals per species and time point.	TiO_2 pulmonary retention half-times for the low-, mid-, and high-exposure groups, respectively: 63, 132, and 365 days in rats; 48, 40, and 319 days in mice; and 33, 37, and 39 days in hamsters. Burden of TiO_2 in lymph nodes increase with time postexposure in mid- and high-dosed rats; in high-dosed mice; but was unaffected in hamsters at any time or dosage group. In high-exposure groups of mice, epithelial permeability remained elevated (~2× control groups) out to 52 wk without signs of recovery. Epithelial permeability was 3-4× control in high exposed rats through 4 wk post exposure, but approached control by 13 wk . Epithelial permeability was unaffected in all groups of hamsters.
Chen et al. (2006, 087947)	Sprague-Dawley male rats (220 ± 20 g)	Polystyrene 125I radiolabel Ultrafine: 56.4 nm Fine: 202 nm	Intratracheal instillation of particles in healthy rats or those pretreated with LPS (12 h before particle instillation). Healthy rats sacrificed between 0.5-2 h and at 24 or 48 h post-instillation. LPS treated rats were sacrificed 0.5-2 h post-instillation.	In healthy rats, there were no marked differences in lung retention or systemic distribution between the ultrafine and fine particles. Results for healthy animals focused on ultrafine particles which were primarily retained in lungs (72 ± 10% at 0.5-2 h; 65 ± 1% at 1 day; 62 ± 5% at 5 days). Initially, there was rapid particle movement into the blood (2 ± 1% at 0.5-2 h; 0.1 ± 0.1% at 5 days) and liver (3 ± 2% at 0.5-2 h; 1 ± 0.1% at 5 days). At 1 day post-instillation, about 13% of the particles where in the urine or feces. Following LPS treatment, ultrafine accessed the blood (5 vs. 2%) and liver (11 vs. 4%) to a significantly greater extent than fine particles.
Geiser et al. (2005, 087362) Also included in in vitro studies	Wistar rats 20 adult males (250 ± 10 g)	TiO_2 (22 nm CMD, 1.7 σg) Spark generated 0.11 mg/m^3 7.3 × 106 particles/cm^3	Rats exposed 1-h via endotracheal tube while anesthetized and ventilated at constant rate. Lungs fixed at 1 or 24-h postexposure.	Distributions of particles among lung compartments followed the volume distribution of compartments and did not differ significantly between 1 and 24-h post-inhalation. On avg, 79.3 ± 7.6% of particles were on the luminal side of the airway surfaces, 4.6 ± 2.6% in epithelial or endothelial cells, 4.8 ± 4.5% in connective tissues, and 11.3 ± 3.9% within capillaries. Particles within cells were not membrane-bound.
Kapp et al. (2004, 156624)	Charles River rats 5 young adult male (250 ± 10 g)	TiO_2 (22 nm CMD, 1.7 σg) Spark generated	Rats exposed 1-h via endotracheal tube while anesthetized and ventilated at constant rate. Lungs fixed immediately postexposure.	Of particles in tissues, 72% were aggregates of 2 or more particles; 93% of aggregates were in round or oval shape aggregates, 7% were needle-like. The size distribution of particles in lung tissues (29 nm CMD, 1.7 σg) was remarkably similar to the aerosol; the small discrepancy may have been due to differences sizing techniques. A large 350 nm aggregate was found in a type II pneumocyte, a 37 nm particle in a capillary close to the endothelial cells, and a 106 nm particle within the surface-lining layer close to the alveolar epithelium.

Table B- 3. In vitro studies of ultrafine disposition.

Reference	Animal	Particles	Study Protocol	Observations
Edetsberger et al. (2005, 155759)	Human cervix carcinoma cells (HeLa cells)	Polystyrene spheres (0.020 µm)	Cells incubated with polystyrene particles having negative surface charges. Cell cultures were naïve or treated with Genistein or Cytochalasin B (CytB) prior to particle application. Genistein inhibits endocytotic processes, expecially caveolae internalization. CytB inhibits actin polymerization and phagocytosis.	Particles translocated into cells by first measurement (~1 min after particle application) independent of treatment group. In naïve cells, agglomerates of 88-117 nm were seen by 15-20 min and of 253-675 nm by 50-60 min after particle application. Intracellular aggregates thought to be result from particle incorporation into endosomes or similar structures. In treated cells, only a small number of agglomerates (161-308 nm) were found and only by 50-60 min. At 50-60 min, 90% and 98% of particles were in the 20-40 nm range in naïve and treated cells, respectively. Particles did not translocate into dead cells, rather they attached to outside of the cell membrane.
Geiser et al. (2005, 087362) Also included inhalation study	Porcine lung macrophages (106 cell/mLuman red blood cells (RBC; 8 × 106 cells/mL)	Fluorescent polystyrene spheres (0.078, 0.2, and 1 µm) Gold shheres (0.025 µm)	Cells cultured for 4 h with each sized polystyrene spheres. RBC were employed as a model of nonphagocytic cells. Some macrophages cultures were treated with cytochalasin D (cytD) to inhibit phagocytosis. In addition, RBC were also cultured with gold particles.	Of the non-cytD treated macrophages, 77 ± 15%, 21 ± 11%, and 56 ± 30% contained 0.078, 0.2, and 1 µm particles, respectively. CytD treatment of macrophages effectively blocked the phagocytosis of 1 µm particles, but did not alter the uptake of the 0.078 and 0.2 µm particles. Human RBC were found to contain 0.078 and 0.2 µm polystyrene spheres as well as the 0.025 µm gold particles, which were not membrane bound. In contrast, the RBC did not contain the larger 1 µm polystyrene spheres. Results suggest that ultrafine and fine (0.078 and 0.2 µm diameter) particles cross cellular membranes by a non-endocytic (i.e. not involving vesicle formation) mechanisms such as adhesive interactions and diffusion.
Geys et al. (2006, 155789)	Human alveolar (A549) and bronchial (Calu-3) epithelial cellsRat primary type II pneumocytes	Amine- and carboxyl-modified fluorescent polystyrene (46 nm)	Cells cultured in clear polyester transwells with 0.4 or 3 µm pores. Monolayer considered "tight" when <1% sodium fluorescein moved from apical to basolateral compartment. Particle translocation assessed in transwells with and without cells. Cells incubated with particles for 14-16 h to assess translocation from apical to basolateral compartment.	Without cells, 13.5% of carboxyl-modified particles passed through the 0.4 µm pores (n = 7) and 67.5% through 3 µm pores (n = 3). Movement of the amine-modified particles was 4.2% through 0.4 µm pores (n = 7) and 52.7% through 3 µm pores (n = 3). The integrity of the monolayer was insufficient for translocation studies using the A549 cells (0.4 and 4 µm pore size) and rat pneumocytes (0.3 µm pore). Using 0.4 µm pores, there was no detectable translocation through either Calu-3 or rat pneumocyte monolayers. Using 3 µm pores, ~6% of both particle types passed through the Calu-3 monolayer; however, results were highly variable with no translocation in 2 (of 5) and 3 (of 6) trials with carboxyl- or amine-modified particles, respectively.

B.2. Olfactory Translocation

Table B-4. Olfactory particle translocation.

Reference	Study Group	Aerosol	Study Protocol	Observations
DeLorenzo (1970, 156391)	Squirrel monkeys Young males (1 kg)	Silver-coated colloidal gold (50 nm)	Intranasal instillation of 1 mL particle suspension. Animals sacrificed at 0.25, 0.5, 1, and 24-h after instillation.	Rapid movement (30-60 min) into olfactory bulbs. Within 30 min of being placed on nasal mucosa, particle aggregates were seen in axoplasm of the fila olfactoria Within 1 h, particles were in olfactory glomerulus. Particles in the olfactory bulb were located preferentially in mitochondria and not free in the cytoplasm.
Dorman et al. (2001, 055433)	Crl: CD rats Males (6 wk old)	Soluble and insoluble Mn particle types; MMAD = 1.3-2.1 µm; GSD<2	Whole body exposure (6 h/day, 14 consecutive days) to 0, 0.03, 0.3, and 3 mg Mn/m^3. Tissues analyzed in six animals per concentration exposed to soluble ($MnSO_4$) or insoluble (Mn_3O_4) aerosols.	Increased Mn levels in olfactory bulb observed following $MnSO_4$ of ≥ 0.3 mg Mn/m^3 and following Mn_3O_4 of 3 mg Mn/m^3. At 3 mg Mn/m^3, Mn levels were significantly greater in olfactory bulb (1.4-fold) and striatum (2.7-fold) following soluble MnO_4 than insoluble Mn_3O_4. Mn levels in the cerebellum were unaffected following all exposures.

Reference	Study Group	Aerosol	Study Protocol	Observations
Dorman et al. (2004, 155752)	Crl: CD rats Males (6 wk old)	Soluble and insoluble Mn particle types; MMAD = 1.5-2 µm; GSD = 1.4-1.6	Whole body exposure (6 h/day, 5 days/wk, 13 wk) to $MnSO_4$ at 0, 0.01, 0.1, and 0.5 mg Mn/m^3. Compared to Mn phosphate (as hureaulite) exposure of 0.1 mg Mn/m^3. Brain Mn levels assessed immediately following 90 days of exposure or 45 days postexposure.	Relative to air, the insoluble hureaulite was significantly increased at 90 days of exposure in the olfactory bulb, but not striatum or cerebellum. The soluble Mn phosphate showed a dose dependent increase in olfactory bulb Mn levels at 90 days. At 0.1 mg Mn/m^3, Mn levels following Mn phosphate were significantly increased in the olfactory bulb and striatum relative to hureaulite and air exposures. At 45 days postexposure, relative to air, olfactory bulb Mn levels only remained increased Mn phosphate group at 0.5 mg Mn/m^3.
Elder et al. (2006, 089253)	Fisher 344 rats Males (200-250 g)	Mn oxide (~30 nm equivalent sphere with 3-8 nm primary particles) Spark generated 0.5 mg/m^3 18 × 106 particles/cm^3	Whole body inhalation exposure to either filtered air or Mn oxide for 12 days (6 h/day, 5 days/wk) with both nares open or Mn oxide for 2 days (6 h/day) with right nostril blocked. Intranasal instillation in left nostril of Mn oxide particles or soluble MnCl2 suspended in 30 µL saline. Analyzed Mn in the lung, liver, olfactory bulb, and other brain regions.	After 12 day exposure via both nostrils, Mn in the olfactory bulb increased 3.5-fold, whereas in the lung Mn concentrations doubled; there were also increases in the striatum, frontal cortex, and cerebellum. After the 2 days exposure with the right nostril blocked, Mn accumulated in the mainly in the left olfactory bulb (~2.4-fold increase) in to a lesser extent in the right olfactory bulb (1.2-fold increase). At 24-h post instillation, the left olfactory bulb contained similar amounts of the poorly soluble Mn oxide (8.2 ± 0.7%) and soluble MnCl2 (8.2 ± 3.6%) as a percent of the amount instilled.
Oberdörster et al. (2004, 055639)	Fisher 344 rats Males (14 wk; 284 ± 9 g)	13C (36 nm CMD, 1.7 σg) Spark generated	Rats (n = 12, 3 per time point) exposed to 160 $µg/m^3$ for 6 h in whole-body chamber and sacrificed at 1, 3, 5, and 7 day postexposure. Lung, olfactory bulb, cerebrum, and cerebellum removed for 13C analysis. Tissue 13C-levels were determined by isotope ratio mass spectroscopy and background corrected for 13C levels in unexposed controls (n = 3).	At 1 day postexposure, the lungs of rats exposed to ultrafine 13C particles contained 1.34 ± 0.22 µg of 13C (1.39 µg/g-lung) following background corrected. By 7 days postexposure, the 13C concentration had decreased to 0.59 µg/g-lung. There was a significant and persistent increase in 13C in the olfactory bulb of 0.35 µg/g on day 1, which increased to 0.43 µg/g by day 7. Day 1 concentrations of 13C in the cerebrum and cerebellum were also significantly increased but the increase was inconsistent, possibly reflecting translocation of particles from the blood across the blood-brain barrier into brain regions.
Persson et al. (2003, 051846)	Sprague-Dawley male rats (150 g) Freshwater Pike female (3 kg)	65ZnCl2 dissolved in 0.1 M HCl	Rats: intransal (0.03 µg Zn in 10 µL) or intraperitoneally (0.03 µg Zn in 100 µL); autoradiography and γ spec at 1 day or 1, 3, or 6 wk postexposure. Pike: instilled (0.12 µg Zn in 10 µL) in right or both olfactory chambers, assayed 2 wk postexposure	Zn uptake in olfactory epithelium and transport along olfactory neurons to olfactory bulb. Zn continued into interior of olfactory bulb and in rat went into anterior olfactory cortex. Zn found bound to both cellular constituents and cytosolic components. Some Zn bound to metallothionein in olfactory mucosa and olfactory bulb.
Wang et al. (2007, 156147)	CD-1 (ICR) mice	Rutile TiO_2 21 and 80 nm Anatase TiO_2 155 nm	Twenty mice (n = 5 per group) exposed 0 or 0.01 g-TiO_2 per mL DI. Instilled 25 µL each day for 5 days, then inhaled 10 µL every other day. Mice sacrificed after 1 mo.	Rutile particles were observed to be column/fiber shaped, whereas anatase was octahedral. TiO_2 particles taken up by olfactory bulb via the olfactory nerve layer, olfactory ventricle, and granular cell layer of the olfactory bulb. Fine TiO_2 showed greater entry into the olfactory bulb presumably due to aggregation of smaller rutile particles that was not seen for the fine anatase particles.
Yu et al. (2003, 156171)	Sprague-Dawley male rats, 6 wk old (218 ± 10 g)	Stainless steel welding-fume <0.5 µm	Whole body exposure 2 h/day for 1, 15, 30, or 60 days Low: 64 ± 4 mg/m^3 (1.6 mg/m^3 Mn) High: 107 ± 6 mg/m^3 (3.5 mg/m^3 Mn)	Significant increases in cerebellum Mn at 15-30 days of exposure. Slight increases in Mn in substantia nigra, basal ganglia, temporal cortex, and frontal cortex after 60 days. Significant increase at 30 days in basal ganglia at low dose. Authors suggested that pharmacokinetics and distribution of welding fume Mn differs from pure Mn.

B.3. Clearance and Age

Table B-5. Studies of respiratory tract mucosal and macrophage clearance as a function of age.

Reference	Animal	Particles	Study Protocol	Observed Effect(s)
NASAL AND TRACHEAL CLEARANCE				
Ho et al. (2001, 156549)	Human, males and females	Not applicable	Ninety subjects (47 M, 43 F; 52 ± 23 yr) between 11 and 90 yr of age were recruited to measure nasal saccharine clearance and ciliary beat frequency.	Ciliary beat frequency (n = 90; r = -0.48, p <0.0001) and nasal mucociliary clearance time (n = 43; r = 0.64, p <0.001) were correlated with subject age. Nasal clearance times were significantly (p <0.001) faster in individuals under 40 yr of age (9.3 ± 5.2 min) versus older subjects (15.4 ± 5.0 min). Results similar between males and females.
Goodman et al. (1978, 071130)	Humans, males and females	Radiolabed Teflon disks (1 mm diameter, 0.8 mm thick)	Tracheal mucus velocity following delivery via bronchoscope to the tracheal mucosa. Ten young (2 M, 8 F; 23 ± 3 yr) and ten elderly (2 M, 5 F; 63 ± 5 yr) nonsmokers served as control subjects. Measurements were also made in young smokers, ex-smokers, and individuals with chronic bronchitis.	Young nonsmokers had a tracheal mucus velocity of 10.1 ± 3.5 mm/min which was significantly faster than the velocity of 5.8 ± 2.6 observed in the elderly nonsmokers.
Whaley et al. (1987, 156153)	Beagle dogs, males and females	Macroaggregated albumin99mTc labelled	Intratracheal instillation of 10- µl droplet of labelled albumin in saline. Tracheal clearance followed 25 min. Longitudinal measure measurements in 5 males and 3 females when young adults (2.8-3 yr), middle-aged (6.7-6.9 yr), and mature (9.6-9.8 yr). Additional 5 females and 3 males comprised immature group (9-10 mo) and 4 males and 4 females used as aged group (13-16 yr).	Tracheal mucus velocity significantly (p <0.05) greater in young (9.7 ± 0.6 [SE] mm/min) and middle-aged (6.9 ± 0.5) groups than in immature (3.6 ± 0.4), mature (3.5 ± 0.8), and aged (2.9 ± 0.5) dogs.
Yeates et al. (1981, 095391)	Humans, males and females	Radioaerosols 99mTc labelled	Tracheal mucus velocities compiled for 74 healthy non-smoking subjects (60 M, 14 F; 10-65 yr, mean 30 yr) from prior studies. Forty-two (32 M, 10 F) inhaled albumin in saline droplets (6.2-6.5 µm MMAD), Yeates et al. (1975); twenty-two (21 M, 1 F) inhaled iron oxide (4.2 µm MMAD), Yeates et al. (1981b); and ten (7 M, 3 F) inhaled monodisperse iron oxide aerosol (7.5 µm MMAD), Leikauf et al. (1981). Inhalations were via a mouthpiece with an inspiratory flow of ~1 liter/sec.	A lognormal distribution of tracheal mucus velocities was reported. Age did not appear to affect velocities, e.g., 4.7 ± 2.5 mm/min in 18-24 yr olds vs. 4.6 ± 3.2 mm/min in individuals >30 yr of age. However, it should be noted that only 2 subjects were greater than 45 yr of age and that the data was complied from three studies using differing experimental techniques. Rather similar tracheal mucus velocities in males (4.7 ± 3.0 mm/min) and females (4.9 ± 2.4 mm/min).
BRONCHI AND BRONCHIOLES CLEARANCE				
Puchelle et al. (1979, 006863)	Human, males	7.4 µm MMAD99mTc labelled resin	Mucociliary clearance measured for 1 h post aerosol inhalation in 19 healthy non-smoking males (21-69 yr of age). Clearance measure on two occasions in 16 individuals.	Negative correlation (r = -0.472, p <0.05) between mucociliary clearance and age. Younger subjects (n = 9; 21-37 yr) had 1-h clearance of 34 ± 14% which was significantly greater than the 22 ± 8% found in the older subjects (n = 5; >54 yr). Separated by 5.4 wk (on avg), there was a good correlation between repeated clearance measurements (r = 0.65, p <0.001)
Svartengren et al. (2005, 157034)	Humans, males and females	6 µm MMAD111In labelled Teflon	Small airway clearance measured in five age groups (≤ 24 yr, n = 13; 25-29 yr, n = 8; 30-49 yr, n = 7; 50-64, n = 9; >65 yr, n = 9) of healthy subjects. Aerosol inhaled via mouthpiece at extremely slow rate of 0.05 L/s. Activity in lungs measured at 1 day, 2 days, and 1, 2, and 3 wk post-exposure. Under the presumption that most large airway clearance was complete by 24 h, retention at 24 h was normalized to 100%.	Large and small airway clearance slowed with increasing age. Clearance correlated with age at all times (r = -0.46 to -0.50, -0.55, -0.66, and -0.70 at 1 day, 2 days, 1 wk, 2 wk, and 3 wk, respectively). Based on linear regression, the clearance from 1 to 21 days post-exposure was 47% in a 20 yr-old versus 23% in an 80 yr-old. Lung function was not a significant predictor of clearance when age considered.

Reference	Animal	Particles	Study Protocol	Observed Effect(s)
Vastag et al. (1985, 157088)	Humans, males and females	Monodisperseerythrocytes99mTc labelled	Clearance measured for 1-h post-inhalation in eighty healthy (59 M, 21 F; 43 ± 17 yr) subjects who had never smoked. Smokers and ex-smokers also studied. Aerosol inhalation not described.	Clearance significantly associated with age. Based on linear regression, total mucociliary clearance at 1-h post-exposure was 46% in a 20 yr old versus 23% in an 80 yr old. Similar results for males and females.
ALVEOLAR CLEARANCE				
Muhle et al. (1990, 006853)	Fischer 344 rats	3.5 µm MMAD 85Sr labelled polystyrene latex	Control animals compared across several studies. Aerosol inhaled by short-term nose only exposure. Alveolar clearance determined by exponential fit to thoracic activity measured over 75-100 days excluding the first 15 days post-exposure.	Typical alveolar clearance half-time of 45 days in 5-mo-old rats compared to 74 days in 23-mo-old rats. Statistical significance of findings not proved.

Annex C.
Controlled Human Exposure Studies

Table C-1. Cardiovascular effects.

Study	Pollutant	Exposure	Findings
Reference: Barregard et al. (2006, 091381) **Subjects:** 13 healthy adults **Gender:** 6 M/7 F **Age:** 20-56 yr	Wood smoke **Particle Size:** Session 1: GMD 42 nm; Session 2: GMD 112 nm **Particle Number/Count:** Session 1: 180,000/cm^3; Session 2: 95,000/cm^3 **Concentration:** Session 1: median: 279 µg/m^3; Session 2: median 243 µg/m^3	Subjects exposed in two groups for 4 h to filtered air, followed a wk later by a 4-h exposure to wood smoke. Exposures conducted with two 25-min periods of light exercise. Other measured combustion products: Session 1: NO_2 (0.08 ppm), CO (13 ppm), formaldehyde (114 µg/m^3), acetaldehyde (75 µg/m^3), benzene (30 µg/m^3), 1,3-butadiene (6.3 µg/m^3); Session 2: NO_2 (0.09 ppm), CO (9.1 ppm), formaldehyde (64 µg/m^3), acetaldehyde (40 µg/m^3), benzene (20 µg/m^3), 1,3-butadiene (3.9 µg/m^3). **Time to analysis**: Immediately following exposure as well as 3 and 20 h post-exposure.	Statistically significant increase in plasma factor VIII 20 h post wood smoke exposure relative to filtered air. The factor VIII/von Willebrand ratio in plasma was increased with wood smoke relative to filtered air at 0, 3, and 20 h post-exposure. Wood smoke exposure increased the urinary excretion of free 8-iso-prostaglandin2α relative to clean air 20 h post-exposure (n = 9). These findings were more pronounced in session 1 than session 2 (similar mass concentration but higher number concentration in Session 1).
Reference: Beckett et al. (2005, 156261) **Subjects:** 12 healthy adults **Gender:** 6 M/6 F **Age:** 23-52 yr	Ultrafine and fine zinc oxide **Particle Size:** UF: <0.1 µm; Fine: 0.1-1.0 µm **Particle Number/Count:** UF: 4.6×10^7/cm^3; Fine: 1.9×10^5/cm^3 **Concentration:** 500 µg/m^3	Subjects exposed via mouthpiece for 2 h during rest to filtered air, ultrafine, and fine zinc oxide in a randomized crossover study design. Exposures were separated by at least 3 wk. **Time to analysis:** Immediately following exposure and 3, 6, 11, 23, and 24 h after exposure.	Exposure to ultrafine and fine zinc oxide did not affect HRV (time and frequency domain parameters) relative to clean air immediately following exposure, or at 3, 6, 11, and 23 h post-exposure. Exposure did not affect blood pressure through 24 h post-exposure. No effects of exposure to either fine or ultrafine zinc oxide observed on factor VII, von Willebrand factor (vWf), tissue plasminogen activator (t-PA), or fibrinogen. No effect of exposure observed on peripheral blood cell counts or levels of pro-inflammatory cytokines.
Reference: Blomberg et al. (2005, 191991) **Subjects:** 15 older adults (former smokers) with COPD **Age:** 56-72 yr	DE **Concentration:** 300 µg/m^3	Subjects exposed for 1 h with intermittent exercise to DE and filtered air in a randomized crossover study design. **Time to analysis:** 6 and 24 h post-exposure.	DE was not observed to affect blood levels of C-reactive protein, fibrinogen, D-Dimer, prothrombin factor 1-2, or von Willebrand factor activity at 6 and 24 h post-exposure.
Reference: Brauner et al. (2007, 091152) **Subjects:** 29 healthy adults **Gender:** 20 M/9 F **Age:** 20-40 yr	Urban traffic particles **Particle Number/Count:** 6–700nm: 10,067/cm^3 **Concentration:** $PM_{2.5}$: 9.7 µg/m^3; $PM_{10\text{-}2.5}$: 12.6 µg/m^3	Subjects exposed to urban traffic particles and filtered air for 24 h with and without two 90-min periods of light exercise in a randomized crossover study design. Concentrations of NO_X and NO were low and did not differ between filtered and unfiltered exposures. CO concentrations were higher with filtered air (0.35 and 0.41 ppm), while O_3 concentrations were lower with filtered air (12.08 and 4.29 ppb). **Time to analysis:** 6 and 24 h after the start of exposure.	An increase in DNA strand breaks and formamidopyrimidine-DNA glycosylase sites in peripheral blood mononuclear cells were observed after 6 and 24 h of exposure to urban particulates. The particle concentration at the 57nm mode was shown to be the major contributor to these effects.

Note: Hyperlinks to the reference citations throughout this document will take you to the NCEA HERO database (Health and Environmental Research Online) at http://epa.gov/hero. Study	Pollutant	Exposure	Findings
Reference: Brauner et al. (2008, 156293) **Subjects:** 42 healthy older adults (21 couples) **Age:** 60-75 yr	Indoor air particles **Particle Number/Count:** 10-700 nm: 10,016/cm^3 **Concentration:** Coarse: 9.4 µg/m^3; Fine: 12.6 µg/m^3	Exposures consisted of two 48 h periods in the home of each subject with or without the use of a HEPA filter (randomized crossover design). HEPA filters reduced coarse concentration from 9.4 to 4.6 µg/m^3,, and fine concentration from 12.6 to 4.7 µg/m^3. Concentrations of NO_2 did not differ between the 2 sessions (20 ppb). **Time to analysis:** After the completion of each 48 h session.	The use of HEPA filters significantly improved microvascular function (p = 0.04) after 48 h (reactive hyperemia-peripheral arterial tonometry). Microvascular function was assessed using a scoring system representing the extent of reactive hyperemia. The reduction in PM concentration through the use of HEPA filters did not significantly affect blood pressure following the 48-h exposures. Lowering PM concentration did not significantly affect inflammatory response markers in peripheral venous blood (IL-6, TNF-α, C-reactive protein, plasma amyloid A).
Reference: Brauner et al. (2008, 191966) **Subjects:** 29 healthy adults **Gender:** 20 M, 9 F **Age:** M avg 27 yr, F avg 26 yr	Urban traffic particles **Particle Number/Count:** 11,600/cm^3 **Concentration:** $PM_{2.5}$: 10.5 µg/m^3; $PM_{10-2.5}$: 13.8 µg/m^3	Subjects exposed to urban traffic particles and filtered air for 24 h with and without two 90-min periods of light exercise in a randomized crossover study design. Concentrations of NO_X and NO were low and did not differ between filtered and unfiltered exposures. CO concentrations were higher with filtered air, while O_3 concentrations were lower with filtered air. **Time to analysis:** 6 and 24 h after the start of exposure.	Exposure to urban traffic particles was not observed to affect microvascular function (digital peripheral artery tone) at 6 or 24 h after the start of exposure. No difference in various blood markers of coagulation, inflammation, or protein oxidation (e.g., fibrinogen, platelet count, CRP, IL-6, TNF- α) were demonstrated between particle and filtered air exposure.
Reference: Carlsten et al. (2007, 155714) **Subjects:** 13 healthy adults **Gender:** 11 M/2 F **Age:** 20-42 yr	DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) operating at load **Concentration:** Fine PM: 100, 200 µg/m^3	Subjects exposed for 2 h at rest to filtered air and each of the two DEPs concentrations in a randomized crossover study design. Exposures were separated by at least 2 wk. Other diesel emissions measured: NO_2 (10-35 ppb), CO (0.7-1.8 ppm). **Time to analysis:** 3, 6, and 22 h after the start of exposure.	No statistically significant changes in plasminogen activator inhibitor-1 (PAI-1), vWf, D-dimer, or platelet count observed 3, 6, or 22 h following exposure to DE relative to filtered air. Non-statistically significant increases in D-dimer, vWf, and platelet count were observed at 6 h following the start of exposure (4 h post-exposure). No diesel-induced increase in C-reactive protein observed relative to filtered air in peripheral venous blood at 1 or 20 h post-exposure.
Reference: Carlsten et al. (2008, 156323) **Subjects:** 16 adults with metabolic syndrome **Gender:** 10 M/6 F **Age:** 25-48 yr	DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) **Concentration:** Fine PM: 100, 200 µg/m^3	Subjects exposed for 2 h at rest to filtered air and each of the two DE particle concentrations in a randomized crossover study design. Exposures were separated by at least 2 wk. Other diesel emissions measured: NO_2 (30 ppb), NO (1.69 ppm), CO (0.65 ppm). **Time to analysis:** 3, 7, and 22 h after the start of exposure.	At 5 h after the end of diesel exposure (fine particulate concentration 200 µg/m^3), the authors observed a significant decrease in vWf in peripheral venous blood. No other changes in thrombotic markers (vWf, D-dimer, PAI-1) were observed at either concentration between 1 and 20 h post-exposure.
Reference: Danielsen et al. (2008, 156382) **Subjects:** 13 healthy adults **Gender:** 6 M/7 F **Age:** 20-56 yr	Wood smoke **Particle Size:** Session 1: GMD 42 nm; Session 2: GMD 112 nm **Particle Number/Count:** Session 1: 180,000/cm^3; Session 2: 95,000/cm^3 **Concentration:** Session 1: median: 279 µg/m^3; Session 2: median 243 µg/m^3	Subjects exposed in two groups for 4 h to filtered air, followed a wk later by a 4-h exposure to wood smoke. Exposures conducted with two 25-min periods of light exercise. Other measured combustion products: Session 1: NO_2 (0.08 ppm), CO (13 ppm), formaldehyde (114 µg/m^3), acetaldehyde (75 µg/m^3), benzene (30 µg/m^3), 1,3-butadiene (6.3 µg/m^3); Session 2: NO_2 (0.09 ppm), CO (9.1 ppm), formaldehyde (64 µg/m^3), acetaldehyde (40 µg/m^3), benzene (20 µg/m^3), 1,3-butadiene (3.9 µg/m^3). **Time to analysis:** 3 and 20 h post-exposure.	Exposure to wood smoke increased the mRNA levels of hOGG1 in PBMCs relative to filtered air 20 h after exposure. DNA strand breaks were shown to decrease in PBMCs 20 h after wood smoke exposure.
Reference: Devlin et al. (2003, 087348) **Subjects:** 10 healthy older adults **Gender:** 7 M/3 F **Age:** Avg 66.9 yr	Fine CAPs (Chapel Hill, NC) **Concentration:** Mean: 40.5 µg/m^3, Range: 21.2-80.3 µg/m^3	Exposures conducted for 2 h at rest to filtered air and CAPs in a randomized crossover study design. **Time to analysis:** Immediately following exposure and 24 h post-exposure.	CAPs exposure resulted in statistically significant reductions (p <0.05) in time domain (PNN50) and frequency domain (HF power) parameters relative to clean air immediately following exposure. These relative decreases were still apparent 24 h after exposure (p <0.08).

Study	Pollutant	Exposure	Findings
Reference: Fakhri et al. (2009, 191914) **Subjects:** 50 adults (40 healthy, 10 asthmatic) **Gender:** 24 M/26 F **Age:** 19-48 yr	Fine CAPs (Toronto) **Concentration:** 127 ± 62 µg/m^3 with and without co-exposure to O_3 (114 ± ppb)	Exposures conducted through a facemask which covered the subject's nose and mouth. Subjects were exposed to CAPs, O_3, CAPs + O_3 and filtered air for 2 h at rest in a randomized crossover study design. **Time to analysis:** Every 30 min during exposure, with the final measurement made immediately prior to the end of the exposure.	Exposure to CAPs or O_3, alone or in combination, resulted in no significant changes in HRV or blood pressure relative to filtered air. However, a negative concentration response relationship was reported between CAPs concentration with co-exposure to O_3 and SDNN, rMSSD, HF power and LF power (statistically significant for LF power). Diastolic blood pressure was observed to increase with exposure to CAPs + O_3, but not with either pollutant alone. There was no difference in response between asthmatics and healthy subjects.
Reference: Frampton et al. (2006, 088665) **Subjects:** 16 asthmatic adults, 40 healthy adults **Gender:** Asthmatics: 8 M/8 F, Healthy: 20 M/20 F **Age:** 18-40 yr	Ultrafine EC **Particle Size:** CMD ~25 nm **Particle Number/Count:** 10 µg/m^3: ~2.0 × 10^6/cm^3; 25 µg/m^3: ~7.0 × 10^6/cm^3; 50 µg/m^3: ~10.8 × 10^6/cm^3 **Concentration:** 10, 25, and 50 µg/m^3	Study conducted using a randomized crossover design with 2-h exposures. Asthmatics (n = 16) exposed to filtered air and 10 µg/m^3. 12 healthy adults exposed to filtered air and 10 µg/m^3 at rest; 12 healthy adults exposed to filtered air, 10 and 25 µg/m^3 with intermittent exercise; 16 healthy adults exposed to filtered air and 50 µg/m^3 with intermittent exercise. Exposures were conducted via mouthpiece. **Time to analysis:** Immediately following exposure as well as 3.5, 21, and 45 h post-exposure.	No effect of ultrafine particle exposure on leukocyte counts or leukocyte expression of adhesion molecules observed in healthy subjects exposed at rest to 10 µg/m^3. Among healthy adults exposed to ultrafine carbon during exercise, monocyte expression of adhesion molecules CD54 and CD18 decreased relative to filtered air immediately following exposure. An ultrafine particle-induced decrease in PMN expression of CD18 was also observed 0-21 h post-exposure. Expression of CD11b on monocytes and eosinophils was reduced following exposure to ultrafine particles in exercising asthmatics 0-21 h post-exposure. A decrease in total leukocyte count was observed following ultrafine particle exposure in exercising healthy and asthmatic subjects.
Reference: Gong et al. (2004, 087964) **Subjects:** 13 older adults with COPD, 6 healthy older adults **Gender:** COPD: 5 M/8 F, Healthy: 2 M/4 F **Age:** COPD: avg 68 yr, Healthy: avg 73 yr	Fine CAPs (Los Angeles) **Particle Size:** 85% of mass between 0.1 and 2.5 µm **Concentration:** Mean: 194 µg/m^3, Range: 135-229 µg/m^3	Exposures to CAPs and filtered air (randomized crossover) for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wk. **Time to analysis:** Immediately following exposure as well as 4 and 22 h post-exposure.	SDNN shown to decrease following CAPs exposure relative to filtered air in healthy older adults (4-22 h post-exposure). No CAPs-induced changes in HRV were observed in older adults with COPD. Ectopic heart beats were observed to increase slightly with CAPs relative to filtered air among healthy subjects, but decreased among subjects with COPD. Exposure to CAPs did not affect platelet or white blood cell count, or levels of fibrinogen, vWF, or factor VII.
Reference: Gong et al. (2004, 055628) **Subjects:** 12 adult asthmatics, 4 healthy adults **Gender:** Asthmatics: 4 M/8 F, Healthy: 2 M/2 F **Age:** Asthmatics: avg 38 yr, Healthy: avg 32 yr	Coarse CAPs (Los Angeles) **Particle Size:** 80% of mass between 2.5 and 10 µm, 20% of mass <2.5 µm **Concentration:** Mean: 157 µg/m^3, Range: 56-218 µg/m^3	Exposures to CAPs and filtered air (randomized crossover) for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wk. **Time to analysis:** Immediately following exposure as well as 4 and 22 h post-exposure.	SDNN shown to decrease following CAPs exposure relative to filtered air in healthy adults (4-22 h post-exposure). Decrease in PNN50 also observed in healthy adults at 4 h post-exposure. No CAPs-induced decreases in HRV demonstrated in asthmatics.
Reference: Gong et al. (2008, 156483) **Subjects:** 14 adult asthmatics, 17 healthy adults **Gender:** Asthmatics: 9 M/5 F, Healthy: 5 M/12 F **Age:** Asthmatics: 34 ± 12 yr, Healthy: 24 ± 8 yr	Ultrafine CAPs (Los Angeles) **Particle Number/Count:** 145,000/cm^3, Range 39,000-312,000/cm^3 **Concentration:** Mean-100 µg/m^3, Range-13-277 µg/m^3	Subjects exposed for 2 h during intermittent exercise (15-min periods) to both CAPs and filtered air in random order. The first 7 subjects underwent whole body exposure, while the remaining subjects were exposed through a facemask. Facemask exposures had higher particle counts but lower particle mass than whole body exposures. Exposures were separated by at least 2 wk. **Time to analysis:** Immediately following exposure as well as 4 and 22 h post-exposure.	Relative to filtered air, exposure to ultrafine CAPs resulted in a transient decrease in LF power 4 h post-exposure. This effect of CAPs on HRV was not influenced by health status. CAPs exposure was not observed to affect any other measures of HRV, blood pressure, or blood markers of inflammation or coagulation. There were no differences in response observed between facemask and whole body exposures.

Study	Pollutant	Exposure	Findings
Reference: Graff et al. (2009, 191981) **Subjects:** 14 healthy adults **Gender:** 8 M/6 F **Age:** 20-34 yr	Coarse CAPs (Chapel Hill, NC) **Concentration:** 89 ± 49.5 µg/m^3 (estimated inhaled dose ≈ 67% of measured particle mass)	Subjects exposed for 2 h with intermittent exercise (15-min periods) to coarse CAPs and filtered air in a randomized crossover design. Exposures were separated by at least 2 mos. **Time to analysis:** 0-1 and 20 h post-exposure.	At 20 h post-exposure, tPA was observed to decrease by 32.9% from baseline (pre-exposure) per 10 µg/m^3 increase in CAPs concentration (p = 0.01). D-dimer concentration decreased 11.3% per 10 µg/m^3, a change of marginal statistical significance (p = 0.07). No other coarse CAPs-induced changes in blood biomarkers of coagulation (e.g., vWF, factor VII, plasminogen, fibrinogen, or PAI-1) or inflammation (e.g., CRP) were observed. At 20 h post-exposure, overall HRV (SDNN) was shown to decrease by 14.4% relative to pre-exposure measurements per 10 µg/m^3 increase in CAPs concentration. No other changes in HRV were observed following exposure to coarse CAPs.
Reference: Huang et al. (2003, 087377) **Subjects:** 38 healthy adults **Gender:** 36 M/2 F **Age:** Avg 26.2 ± 0.7 yr	Fine CAPs (Chapel Hill, NC) **Concentration:** 23.1-311.1 µg/m^3	Subjects exposed to CAPs (n = 30) or filtered air (n = 8) for 2 h with intermittent exercise (subjects did not serve as their own controls). Component data of CAPs was available for 37 of the 38 subjects. **Time to analysis:** 18 h after exposure.	The increase in blood fibrinogen following exposure to fine CAPs reported by Ghio et al. (2000, 012140) was shown to be associated with copper, zinc, and vanadium content in the CAPs.
Reference: Larsson et al. (2007, 091375) **Subjects:** 16 healthy adults **Gender:** 10 M/6 F **Age:** 19-59 yr	Traffic particles (road tunnel) **Particle Size:** $PM_{2.5}$, PM_{10}; $PM_{2.5}$ mass constituted ~36% of PM_{10} mass **Particle Number/Count:** 20-1,000 nm: 1.1 × 10^5/cm^3, < 100 nm: 0.85 × 10^5/cm^3 **Concentration:** $PM_{2.5}$-46-81 µg/m^3; PM_{10}-130-206 µg/m^3	Exposures were conducted for 2 h with intermittent exercise in a room adjacent to a busy road tunnel. Study used a randomized crossover design with each subject also exposed to normal air (control). Exposures were separated by 3-10 wk. No exposures to filtered air were conducted. Other traffic emissions measured: NO (874 µg/m^3), NO_2 (230 µg/m^3), CO (5.8 µg/m^3 reported, likely 5.8 mg/m^3). **Time to analysis:** 14 h post-exposure.	No change in plasma levels of fibrinogen or PAI-1 observed 14 h post-exposure.
Reference: Lucking et al. (2008, 191993) **Subjects:** 20 healthy adults **Gender:** M **Age:** 21-44 yr	DE Protocol 1 (n=8): idling Deutz diesel engine (F3M2011, 2.2 L, 500 rpm) using gas oil Protocol 2 (n=12): idling Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) using Gasoil E10 **Particle Number/Count:** Protocol 1: 1.2 × 10^6/cm^3; Protocol 2: 1.26 × 10^6/cm^3 **Concentration:** Protocol 1: 348 µg/m^3, Protocol 2: 330 µg/m^3	In both protocols, exposures were conducted with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover design with exposures separated by at least one wk. Protocol 1 (n=8): Exposures conducted for 2 h. Other diesel emissions measured: NO_X (0.58 ppm), NO_2 (0.23 ppm), NO (0.36 ppm), CO (3.54 ppm), total hydrocarbon (2.8 µg/m^3). **Time to analysis:** 6 h post-exposure. Protocol 2 (n=12): Exposures conducted for 1h. Other diesel emissions measured: NO_X (2.78 ppm), NO_2 (0.62 ppm), NO (2.15 ppm), CO (3.08 ppm), total hydrocarbon (1.58 µg/m^3). **Time to analysis:** 2 and 6 h post-exposure.	Thrombus formation was observed to increase with diesel 2 and 6 h post-exposure using an ex vivo perfusion chamber. Both platelet-neutrophil and platelet-monocyte aggregates increased relative to filtered air 2 h following exposure to diesel (only evaluated in Protocol 2). Plasma concentrations of soluble CD40L were also observed to increase with diesel. Exposure to diesel was not shown to affect total leukocyte, monocyte, or platelet counts.
Reference: Lund et al. (2009, 180257) **Subjects:** 10 healthy adults **Gender:** 4 M/6 F **Age:** 18-40 yr	DE Idling Cummins diesel engine (5.9 L) using commercial No. 2 fuel **Particle Size:** MMAD 0.10 µm **Concentration:** 100 µg/m^3	Subjects exposed for 2 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Other diesel emissions measured: NO_X (4.7 ppm), NO_2 (0.8 ppm), CO (2.8 ppm), total hydrocarbons (2.4 ppm). **Time to analysis:** 30 min and 24 h post-exposure.	Exposure to diesel resulted in an increase in MMP-9 plasma concentration and activity as well as an increase in endothelin-1 plasma concentration at both 30 min and 24 h post-exposure.

Study	Pollutant	Exposure	Findings
Reference: Lundback et al. (2009, 191967) **Subjects:** 12 healthy adults **Gender:** M **Age:** 21-30 yr	DE Idling Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) using Gasoil E10 **Particle Number/Count:** $1.26 \times 10^6/cm^3$ **Concentration:** 330 $\mu g/m^3$	Subjects exposed for 1 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by at least one wk. Other diesel emissions measured: NO_X (2.78 ppm), NO_2 (0.62 ppm), NO (2.15 ppm), CO (3.08 ppm), total hydrocarbon (1.58 $\mu g/m^3$). **Time to analysis:** 10, 20, 30, and 40 min post-exposure.	Diesel-induced increase in arterial stiffness (increases in augmentation pressure and augmentation index, as well as decrease in time to wave reflection) observed at 10 and 20 min post-exposure using radial artery pulse wave analysis. No effect of diesel observed on carotid-femoral pulse wave velocity which was assessed 40 min post-exposure, but not at earlier time points. No effect of diesel observed on blood pressure 10-30 min post-exposure.
Reference: Mills et al. (2005, 095757) **Subjects:** 30 healthy adults **Gender:** M **Age:** 20-38 yr	DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) **Particle Number/Count:** $1.2 \times 10^6/cm^3$ **Concentration:** 300 $\mu g/m^3$	Subjects exposed for 1 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by two wk. Other diesel emissions measured: NO_2 (1.6 ppm), NO (4.5 ppm), CO (7.5 ppm), total hydrocarbon (4.3 ppm), formaldehyde (0.26 $\mu g/m^3$). **Time to analysis:** 2-4 h post-exposure for 15 subject; 6-8 h post-exposure for the other 15 subjects.	Forearm blood flow increase (induced by bradykinin, acetylcholine, and sodium nitroprusside) was attenuated by DE 2 and 6 h post-exposure. A 6 mmHg increase in diastolic blood pressure ($p = 0.08$) 2 h following exposure to DE was observed relative to filtered air control. Bradykinin-induced release of t-PA was attenuated by diesel exposure 6 h post-exposure. DE did not affect the release of t-PA 2 h post-exposure. No diesel-induced changes in serum IL-6 or TNF-α observed 6 h post-exposure.
Reference: Mills et al. (2007, 091206) **Subjects:** 20 older adults with prior myocardial infarction **Gender:** M **Age:** 60 ± 1 yr	DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) using low sulfur gas-oil E10 **Particle Size:** Median particle diameter 54 nm, Range 20-120 nm **Particle Number/Count:** $1.26 \times 10^6/cm^3$ **Concentration:** 300 $\mu g/m^3$	Subjects exposed for 1 h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by at least two wk. Other diesel emissions measured: NO_X (4.45 ppm), NO_2 (1.01 ppm), NO (3.45 ppm), CO (2.9 ppm), total hydrocarbon (2.8 ppm). **Time to analysis:** During exposure and 6-8 h post-exposure.	A greater increase in exercise induced ST-segment depression and ischemic burden was observed during exposure to DE than clean air. No diesel-induced effects on vasomotor dysfunction observed 6 h post-exposure. Bradykinin-induced release of t-PA was attenuated by diesel exposure relative to filtered air 6 h post-exposure. Effect of diesel on t-PA release was not evaluated at earlier times post-exposure. No diesel-induced changes in blood leukocyte counts or serum C-reactive protein 6 h post-exposure.
Reference: Mills et al. (2008, 156766) **Subjects:** 12 adults with coronary heart disease, 12 healthy adults **Gender:** M **Age:** CHD: 59 ± 2 yr, Healthy: 54 ± 2 yr	Fine CAPs (Edinburgh, Scotland, UK) **Particle Size:** Mean 1.23 µm **Particle Number/Count:** $99{,}400/cm^3$ **Concentration:** 190 ± 37 $\mu g/m^3$	Exposures conducted for 2 h with intermittent exercise. Subjects exposed to CAPs and filtered air using a randomized crossover design with exposures separated by at least 2 wk. **Time to analysis:** 2, 6-8, and 24 h post-exposure.	CAPs exposure had no significant effect on vascular function in healthy adults or adults with coronary heart disease 6-8 h post-exposure (i.e., no change in forearm blood flow as assessed using venous occlusion plethysmography). The authors attributed this lack of response to a low concentration of combustion-derived particles. Small increase in blood platelet and monocyte concentration observed following CAPs exposure. Exposure to CAPs did not affect serum CRP concentration or total leukocyte or neutrophil count.
Reference: Peretz et al. (2007, 156853) **Subjects:** 5 healthy adults **Gender:** M **Age:** 20-31 yr	DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L); operating at 75% of rated capacity **Concentration:** Fine PM 50, 100, 200 $\mu g/m^3$	Subjects exposed for 2 h at rest to filtered air and each of the three DE particle concentrations in a randomized crossover study design. Exposures were separated by at least 2 wk. Other diesel emissions measured, 200 $\mu g/m^3$ exposure: NO_2 (23 ppb), NO (1.75 ppm), CO (1.58 ppm). **Time to analysis:** 6 and 22 h after the start of exposure.	PBMC expression of 10 genes involved in the inflammatory response were observed to be significantly affected by exposure to DE at the highest concentration tested (8 upregulated, 2 downregulated) 6 h after the start of exposure. The expression of 4 genes (1 upregulated, 3 downregulated) associated with the inflammatory response showed significant changes 22 h after diesel exposure. PBMC expression of 5 genes involved in the oxidative stress pathways showed significant changes at 6 h after the start of diesel exposure at the highest concentration tested (4 upregulated, 1 downregulated). 7 genes involved in the oxidative stress pathways showed significant changes at 22 h following exposure (4 upregulated, 3 downregulated).

Study	Pollutant	Exposure	Findings
Reference: Peretz et al. (2008, 156854) **Subjects:** 17 adults with metabolic syndrome, 10 healthy adults **Gender:** Metabolic syndrome: 11 M/6 F, Healthy: 8 M/2 F **Age:** Metabolic syndrome: 20-48 yr, Healthy: 20-42 yr	DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) using No. 2 undyed on-highway fuel; operating at 75% of rated capacity **Particle Size:** Median particle diameter 1.04 µm **Concentration:** Fine PM 100, 200 µg/m^3	Subjects exposed for 2 h at rest to both concentrations of DE as well as filtered air in a randomized crossover design. Exposures were separated by at least 2 wk. Other diesel emissions measured, 100 µg/m^3 exposure: NO_2 (16.5 ppb), NO (0.96 ppm), CO (0.51 ppm); 200 µg/m^3 exposure: NO_2 (24.7 ppb), NO (1.54 ppm), CO (0.89 ppm). **Time to analysis:** Immediately following exposure (within 30 min post-exposure) and 3 h from the start of exposure.	Exposure to 200 µg/m^3 elicited a statistically significant decrease in brachial artery diameter relative to filtered air immediately following exposure. A smaller decrease in brachial artery diameter was also observed following exposure to DE at 100 µg/m^3. Plasma levels of endothelin-1 were observed to increase following DE exposure (200 µg/m^3). The observed effects were more pronounced in healthy subjects than in subjects with metabolic syndrome. DE did not affect endothelium-dependent flow-mediated dilatation. No effect of DE on blood pressure was demonstrated immediately following exposure.
Reference: Peretz et al. (2008, 156855) **Subjects:** 13 adults with metabolic syndrome, 3 healthy adults **Gender:** Metabolic syndrome: 8 M/5 F, Healthy: 3 M/0 F **Age: M**etabolic syndrome: 31-48 yr, Healthy: 24-39 yr	DE 2002 Cummins B-series diesel engine (6BT5.9G6, 5.9 L) using No. 2 undyed on-highway fuel; operating at 75% of rated capacity **Concentration:** Fine PM 100, 200 µg/m^3	Subjects exposed for 2 h at rest to both concentrations of DE as well as filtered air in a randomized crossover design. Exposures were separated by at least 2 wk. Other diesel emissions measured, 100 µg/m^3 exposure: NO_2 (20.6 ppb), NO (0.95 ppm), CO (0.47 ppm); 200 µg/m^3 exposure: NO_2 (28.3 ppb), NO (1.63 ppm), CO (0.74 ppm). **Time to analysis:** 1, 3, 6, and 22 h from the start of exposure.	Exposure to 200 µg/m^3 increased HF power and decreased the LF/HF ratio 1h post-exposure; however, this effect was not consistent across subjects. No effect of DE was observed at later time points. Subjects with metabolic syndrome did not experience greater changes in HRV than healthy subjects.
Reference: Power et al. (2008, 191982) **Subjects:** 5 adults with mild-to-moderate allergic asthma **Gender:** 1 M/4 F **Age:** 28-51 yr	Carbon and ammonium nitrate particles **Concentration:** With co-exposure to 0.2ppm O_3: 255 µg/m^3, Without co-exposure to 0.2ppm O_3: 313 µg/m^3	Subjects exposed for 4 h with intermittent exercise (30-min periods) to filtered air, particles, and particles + O_3 in a crossover study design. Exposures were separated by at least 3 wk. **Time to analysis:** 3 h 40 min from the start of exposure.	Time and frequency domain HRV parameters were not affected by particle exposure relative to filtered air. However, exposure to particles with O_3 resulted in a significant decrease in SDNN as well as changes to both high and low frequency power normalized to the difference between total and very low frequency power.
Reference: Routledge et al. (2006, 088674) **Subjects:** 20 older adults with coronary artery disease, 20 healthy older adults **Gender:** CAD: 17 M/3 F, Healthy: 10 M/10 F **Age:** CAD: 52-74 yr, Healthy: 56-75 yr	Ultrafine carbon **Particle Size:** <10-300 nm; mode at 20-30 nm **Concentration:** Ultrafine carbon: 50 µg/m^3; SO_2: 200 ppb	Exposures conducted (head dome system) to filtered air, ultrafine carbon, SO_2, and ultrafine carbon + SO_2 for 1 h at rest using a randomized crossover study design. **Time to analysis:** Immediately following exposure as well as 3 and 23 h post-exposure.	No PM-induced changes in HRV observed among subjects with coronary artery disease. Among healthy subjects, small increase in HRV (RR, SDNN, rMSSD, and LF power) demonstrated immediately post-carbon exposure. Relative to filtered air control, exposure to ultrafine carbon did not significantly affect blood pressure in healthy adults or adults with coronary artery disease 0-3 h post-exposure. Exposure to ultrafine carbon, either alone or with SO_2, did not affect plasma levels of fibrinogen or D-dimer at 3 or 23 h post-exposure. Exposure to ultrafine carbon did not affect peripheral blood leukocyte count or C-reactive protein levels 3 or 23 h post-exposure.
Reference: Rundell and Caviston (2008, 191986) **Subjects:** 15 healthy college athletes **Gender:** M **Age:** Avg 19.5 yr	Gasoline emissions 2.5 hp gasoline engine running 10 s each min during exposure and in the min prior to exposure **Particle Size:** PM1.0 **Particle Number/Count:** Trial 1: 336,730 ± 149,206/cm^3; Trial 2: 396,200 ± 82,564/cm^3	Subjects were exposed twice to both clean air and dilute gasoline exhaust during 6-min periods of maximal exercise on a cycle ergometer. Clean air exposures occurred first and were separated by 3 days. Gasoline exhaust exposures were also separated by 3 days, with the first occurring 7 days after the second clean air exposure. Other emissions measured: CO (6.3 ± 3.4 ppm). **Time to analysis:** 6 min	There was no difference in total work done (kJ) between the clean air exposures or between the clean air exposures and the first exposure to gasoline exhaust. However, the second gasoline exhaust exposure was demonstrated to significantly decrease work accumulated over the 6min exercise period compared with either of the other exposure conditions ($p < 0.01$).

Study	Pollutant	Exposure	Findings
Reference: Samet et al. (2007, 156940) **Subjects:** Ultrafine CAPs: 20 healthy adults, Coarse CAPs: 14 healthy adults **Gender:** Ultrafine CAPs: 11 M/9 F, Coarse CAPs: 8 M/6 F **Age:** Ultrafine CAPs: 18-35 yr, Coarse CAPs: 18-35 yr	CAPs (Chapel Hill, NC) **Particle Size:** Ultrafine 0.049 ± 0.009 µm; Coarse 3.59 ± 0.58 µm **Concentration:** Ultrafine 47.0 ± 20.2 µg/m^3; Coarse 89.0 ± 49.5 µg/m^3	Preliminary report comparing effects of controlled exposures to coarse, fine, and ultrafine CAPs among healthy adults (3 separate studies). A randomized crossover design was used in evaluating effects of coarse CAPs (n=14) and ultrafine CAPs (n=20) relative to filtered air following 2-h exposures with intermittent exercise. Results compared with previous study of controlled exposure to fine CAPs (Chapel Hill, NC) where subjects did not serve as their own controls (Ghio et al., 2000, 012140). **Time to analysis:** 0-20 h post-exposure.	Statistically significant decrease in SDNN observed 20 h following exposure to coarse CAPs relative to filtered air. Subjects in the high ultrafine CAPs group experienced a decrease in SDNN based on an analysis of 24 h ambulatory Holter monitoring relative to filtered air. Fine CAPs did not significantly affect HRV. Increased levels of D-dimer observed 18 h following exposure to ultrafine CAPs. No CAPs-induced changes in plasma factor VII, plasminogen, fibrinogen, PAI-1, vWf, or t-PA. No CAPs-induced changes in C-reactive protein levels were observed.
Reference: Samet et al. (2009, 191913) **Subjects:** 19 healthy adults **Gender:** 10 M/9 F **Age:** 18-35 yr	Ultrafine CAPs (Chapel Hill, NC) **Particle Size:** < 0.16 µm **Particle Number/Count:** 120,662 ± 48,232 particles/cm^3 **Concentration:** 49.8 ± 20 µg/m^3	Subjects exposed for 2 h with intermittent 15 periods of exercise to UF CAPs and filtered air using a randomized crossover study design. **Time to analysis:** Immediately following exposure and 1 and 18 h post-exposure.	UF CAPs exposure resulted in an increase in plasma concentrations of D-dimer both immediately following exposure (20.6% increase per 10^5 particles/cm^3) as well as 18 h post-exposure (18.2% increase per 10^5 particles/cm^3). Plasma concentration of PAI1 also increased with UF CAPs, although this increase was not statistically significant (24% increase, p = 0.1). No UF CAPs-induced changes observed in plasma concentrations of tPA, vWF, CRP, fibrinogen, plasminogen, or Factor VII. HF and LF power were both observed to increase with UF CAPs exposure relative to filtered air at 18 h post-exposure (41.8% and 36%, respectively, per 10^5 particles/cm^3 increase in UF CAPs). UF CAPs expressed as mass concentration was not observed have a statistically significant effect in HF total power. UF CAPs was not observed to affect time domain measures of HRV over 24 h. The QT interval was shown to decrease both immediately following and at 18 h post exposure (not statistically significant immediately following exposure).
Reference: Shah et al. (2008, 156970) **Subjects:** 16 healthy adults **Age:** 26.9 ± 6.9 yr	Ultrafine EC **Particle Number/Count:** 10.8 ± 1.7 × 10^5 /cm^3 **Concentration:** 50 µg/m^3	Exposures conducted via mouthpiece for 2 h with intermittent exercise to filtered air and ultrafine carbon in a randomized crossover study design. **Time to analysis:** Immediately following exposure as well as 3.5, 21, and 45 h post-exposure.	Exposure to ultrafine carbon attenuated peak forearm blood flow after ischemia relative to filtered air 3.5 h post-exposure. Venous nitrate levels were significantly lower at 21 h following exposure to UF carbon compared with filtered air exposure. PM exposure was not observed to affect blood pressure relative to filtered air at times 0-45 h post-exposure.
Reference: Tornqvist et al. (2007, 091279) **Subjects:** 15 healthy adults **Gender:** M **Age:** 18-38 yr	DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) **Concentration:** 300 µg/m^3	Subjects exposed for 1h with intermittent exercise (15-min periods) to DE and filtered air in a randomized crossover study design. Exposures were separated by at least two wk. Other diesel emissions measured: NO_X (4.44 ppm), NO_2 (0.82 ppm), NO (3.62 ppm), total hydrocarbon (2.21 ppm). **Time to analysis:** 24 h post-exposure.	DE was observed to significantly attenuate endothelium-dependent vasodilation 24 h post-exposure. Endothelium-independent vasodilation was not affected by diesel exposure. Exposure to DE did not affect blood pressure relative to filtered air 24 h after exposure. DE significantly increased plasma levels of IL-6 and TNF-α 24 h following exposure. Exposure to diesel resulted in an increase in total antioxidant capacity of plasma relative to filtered air 24 h post-exposure.
Reference: Urch et al. (2004, 055629) **Subjects:** 24 healthy adults **Gender:** 14 M/10 F **Age:** 35 ± 10 yr	Fine CAPs (Toronto) **Concentration:** 150 µg/m^3 (range 101-257 µg/m^3) with 120 ppb O_3	Exposures conducted through a facemask which covered the subject's nose and mouth. Subjects were exposed to CAPs + O_3 and filtered air for 2 h at rest in a randomized crossover study design. Exposures were separated by at least 2 days. **Time to analysis:** Immediately following exposure.	CAPs + O_3 exposure resulted in a significant decrease in brachial artery diameter immediately post-exposure (Brook et al., 2002, 024987), which was demonstrated to be associated with both the organic and EC fractions of the CAPs.

Study	Pollutant	Exposure	Findings
Reference: Urch et al. (2005, 081080) **Subjects:** 23 healthy adults **Gender:** 13 M/10 F **Age:** 32 ± 10 yr	Fine CAPs (Toronto); **Concentration:** 150 µg/m^3 (range 102-214 µg/m^3) with 120 ppb O_3	Exposures conducted through a facemask which covered the subject's nose and mouth. Subjects were exposed to CAPs + O_3 and filtered air for 2 h at rest in a randomized crossover study design. **Time to analysis:** Every 30 min during exposure, with the final measurement made immediately prior to the end of the exposure.	An increase in diastolic blood pressure of 6 mmHg was observed at the end of CAPs + O_3 exposure, which was statistically different from the change in blood pressure experienced during exposure to filtered air (1 mmHg). This effect was associated with the organic fraction of $PM_{2.5}$.
Reference: Zareba et al. **(2009, 190101)** **Subjects:** 24 healthy adults **Gender:** 12 M/12 F **Age:** 18-40 yr	Ultrafine EC **Particle Size:** Count median diameter 25 nm **Particle Number/Count:** 2×10^6/cm^3 (10 µg/m^3), 7×10^6/cm^3 (25 µg/m^3) **Concentration:** 10 µg/m^3; 25 µg/m^3	Protocol 1 (n=12, 6 M/6 F): Subjects exposed to 10 µg/m^3 UF carbon and filtered air for 2 h at rest in a randomized crossover design. Exposures were separated by at least 2 wk. Protocol 2 (n=12, 6 M/6 F): Subjects exposed to 10 µg/m^3, 25 µg/m^3, and filtered air for 2 h with intermittent exercise (15-min periods) in a restricted randomized crossover design (all subjects exposed to 10 µg/m3 before 25 µg/m3). Exposures were separated by at least 2 wk. **Time to analysis (both protocols):** Immediately following exposure and 3.5 and 21 h post-exposure.	Exposure to 10 µg/m^3 at rest resulted in no change in HRV frequency domain parameters relative to filtered air exposure. Time domain parameters were observed to increase slightly with UF carbon exposure (10 µg/m^3 at rest), however, only the increase in rMSSD was statistically significant (p = 0.032). Some trends toward less shortening of QT interval, increase in ST segment, and increase in variability of repolarization (variability of T wave complexity) were observed with exposure to 10 µg/m^3 at rest, none of which were statistically significant. In Protocol 2, exposure to 10 µg/m^3 UF carbon was observed to slightly increase HRV time domain parameters as was demonstrated in Protocol 1. However, this was not observed at the higher concentration (25 µg/m^3). As with exposure at rest, exposure to UF carbon during exercise was observed to affect repolarization (reduction in QT duration and increase in T-wave amplitude), although this effect was not statistically significant.

Table C-2. Respiratory effects.

Reference	Pollutant	Exposure	Findings
Reference: Alexis et al. (2006, 154323) **Subjects:** 9 healthy adults **Gender:** 3 M/6 F **Age:** 18-35 yr	Coarse fraction particles (Chapel Hill, NC) Heat-treated (biologically inactive) and non-heated particles **Particle Size:** MMAD 5 µm **Concentration:** 0.65 mg per subject	Subjects were administered heat-treated $PM_{10-2.5}$, non-heated $PM_{10-2.5}$, and 0.9% saline (control) via nebulization in a randomized crossover study design. Exposures were separated by at least 1 wk. **Time to analysis:** 2-3 h post-inhalation.	Both heat-treated and non-heated coarse PM were observed to increase neutrophil counts in induced sputum 2-3 h post-inhalation. Biologically active PM (non-heated) induced an increase expression of macrophage TNF-α mRNA, eotaxin, and immune surface phenotypes on macrophages (mCD14, CD11b/CR3, and HLA-DR).
Reference: Barregard et al. (2008, 155675) **Subjects:** 13 healthy adults **Gender:** 6 M/7 F **Age:** 20-56 yr	Wood smoke **Particle Size:** Session 1: geometric mean diameter 42 nm, Session 2: geometric mean diameter 112 nm **Particle Number/Count:** Session 1: 180,000/cm^3; Session 2: 95,000/cm^3 **Concentration:** Session 1: median 279 µg/m^3; Session 2: median 243 µg/m^3	Subjects exposed in two groups for 4 h to filtered air, followed a wk later by a 4-h exposure to wood smoke. Exposures conducted with two 25-min periods of light exercise. Other measured combustion products: Session 1: NO_2 (0.08 ppm), CO (13 ppm), formaldehyde (114 µg/m^3), acetaldehyde (75 µg/m^3), benzene (30 µg/m^3), 1,3-butadiene (6.3 µg/m^3); Session 2: NO_2 (0.09 ppm), CO (9.1 ppm), formaldehyde (64 µg/m^3), acetaldehyde (40 µg/m^3), benzene (20 µg/m^3), 1,3-butadiene (3.9 µg/m^3). **Time to analysis:** Immediately following exposure as well as 3 and 20 h post-exposure.	Relative to filtered air, exposure to wood smoke was observed to increase levels of eNO 3 h post-exposure. Serum Clara cell protein increased 20 h after wood smoke exposure. Wood smoke was observed to increase levels of malondialdehyde in breath condensate immediately after as well as 20 h post-exposure. Effects of wood smoke on eNO and malondialdehyde levels were similar between the two sessions of wood smoke exposure. However, serum Clara cell protein was significantly increased with wood smoke in session 1 (higher particle count) but not in session 2.
Reference: Bastain et al. (2003, 098690) **Subjects:** 18 nonsmoking adults with positive allergy skin test to short ragweed **Gender:** 7 M/11 F **Age:** 18-38 yr	DEP Isuzu diesel engine, 4 cylinder, 4JB1 **Concentration:** 0.3 mg in 200 µl saline	Subjects underwent nasal provocation challenge (intranasal spray) with allergen and either DEP or placebo (saline) in a randomized crossover study design. Challenges were separated by 30 days. This protocol was then repeated 30 days after the last exposure. **Time to analysis:** 24 h post-exposure and 4 and 8 days after exposure.	DEP significantly increased allergic responses to short ragweed. Relative to allergen + placebo, allergen + DEP increased allergen specific IgE 4days following exposure, and increased IL-4 1 day post-exposure. The enhancement of allergic response with DEP was observed to be reproducible within subjects.
Reference: Beckett et al. (2005, 156261) **Subjects:** 12 healthy adults **Gender:** 6 M/6 F **Age:** 23-52 yr	Ultrafine and fine zinc oxide **Particle Size:** UF: <0.1 µm; Fine: 0.1-1.0 µm **Particle Number/Count:** UF: $4.6 \times 10^7/cm^3$; Fine: $1.9 \times 10^5/cm^3$ **Concentration:** 500 µg/m^3	Subjects exposed via mouthpiece for 2 h during rest to filtered air, ultrafine, and fine zinc oxide in a randomized crossover study design. Exposures were separated by at least 3 wk. **Time to analysis:** 11 and 24 h after exposure.	No changes observed in neutrophil count in induced sputum. No PM (zinc oxide)-induced changes in respiratory symptoms observed 0-24 h post-exposure.
Reference: Behndig et al. (2006, 088286) **Subjects:** 15 healthy adults **Gender:** 8 M/7 F **Age:** 21-27 yr	DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) **Particle Size:** PM_{10}; majority of PM mass made up of particles < 1 µm in diameter **Concentration:** 100 µg/m^3	Exposures conducted for 2 h with intermittent exercise to both DE and filtered air in a randomized crossover design. Exposures were separated by at least 3 wk. Other diesel emissions measured: NO_X (1.8 ppm), NO_2 (0.4 ppm), NO (1.3 ppm), CO (10.4 ppm), total hydrocarbons (1.3 ppm). **Time to analysis:** 18 h post-exposure.	Exposure to DE increased neutrophil and mast cell numbers in bronchial mucosa at 18 h post-exposure. Neutrophils, IL-8, and myeloperoxidase observed to increase in bronchial lavage fluid following exposure relative to filtered air. No inflammatory response observed in the alveolar compartment. Exposure to DE increased urate and reduced glutathione bronchoalveolar lavage at 18 h post-exposure.
Reference: Blomberg et al. (2005, 191991) **Subjects:** 15 older adults (former smokers) with COPD **Age:** 56-72 yr	DE **Concentration:** 300 µg/m^3	Subjects exposed for 1 h with intermittent exercise to DE and filtered air in a randomized crossover study design. **Time to analysis:** 6 and 24 h post-exposure.	DE was not observed to affect levels of Clara cell protein in peripheral blood at 6 and 24 h post-exposure.

Reference	Pollutant	Exposure	Findings
Reference: Bosson et al. (2007, 156286) **Subjects:** 16 healthy adults **Gender:** 7 M/9 F **Age:** 20-28 yr	DE Idling Volvo diesel engine **Concentration:** PM 300 µg/m^3 followed by exposure to filtered air or 0.2 ppm O_3	Subjects exposed to DE for 1 h followed 5 h later by a 2-h exposure to either filtered air or O_3 (0.2 ppm) using a randomized crossover study design. All exposures were conducted with subjects engaged in intermittent exercise. **Time to analysis:** 18 h after second exposure (filtered air or O_3).	The percentage of neutrophils and concentration of myeloperoxidase in induced sputum (18 h post-O_3/air exposure) was significantly higher following diesel + O_3 than diesel + air.
Reference: Bosson et al. (2008, 196659) **Subjects:** 14 healthy adults **Gender:** 9 M/5 F **Age:** 21-29 yr	DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders) **Concentration:** PM 300 µg/m^3 or filtered air followed by exposure to 0.2 ppm O_3	Subjects exposed to DE or filtered air for 1h followed 5 h later by a 2-h exposure to O_3 (0.2 ppm) using a randomized crossover study design. All exposures were conducted with subjects engaged in intermittent exercise. Other diesel emissions measured: NO_2 (0.51 ppm), NO (1.65 ppm), total hydrocarbons (1.18 ppm). **Time to analysis:** 24 h after the start of the initial exposure.	Neutrophil and macrophage numbers in bronchial wash were significantly increased 16 h following O_3 exposure when preceded by exposure to diesel, compared to O_3 exposure preceded by exposure to filtered air.
Reference: Brauner et al. (2009, 190244) **Subjects:** 29 healthy adults **Gender:** 20 M, 9 F **Age: M** avg 27 yr, F avg 26 yr	Urban traffic particles **Particle Size:** $PM_{2.5}$, $PM_{10-2.5}$ **Particle Number/Count:** 6-700 nm: 10,067/cm^3 **Concentration:** $PM_{2.5}$: 9.7 µg/m^3, $PM_{10-2.5}$: 12.6 µg/m^3	Subjects exposed to urban traffic particles and filtered air for 24 h with and without two 90-min periods of light exercise in a randomized crossover study design. Concentrations of NO_X and NO were low and did not differ between filtered and unfiltered exposures. CO concentrations were higher with filtered air (0.35 and 0.41 ppm), while O_3 concentrations were lower with filtered air (12.08 and 4.29 ppb). **Time to analysis:** 2.5, 6, and 24 h after the start of exposure.	Epithelial membrane integrity and blood-gas barrier permeability, assessed using pulmonary clearance of 99mTc-labeled diethylenetriamine pentaacetic acid (DTPA), was observed to increase with exercise, but was not affected by exposure to urban particles (2.5 h of exposure). Exposure to urban particles was not shown to affect plasma or urine concentration of Clara cell 16 protein at 6 and 24 h after the start of exposure. No relationship between exposure and pulmonary function was observed at 2.5 h.
Reference: Gilliland et al. (2004, 156471) **Subjects:** 19 adults with allergic rhinitis and positive skin test to ragweed, GSTM1 (14 null, 5 present); GSTT1 (9 null, 10 present); GSTP1 codon 105 variants (13 I/I, 6 I/V, 0 V/V) **Gender:** 7 M/12 F **Age:** 20-34 yr	DEP Isuzu diesel engine, 4 cylinder, 4JB1 **Concentration:** 0.3 mg DEP in 300 µL saline	Subjects were challenged intranasally with allergen and placebo (saline) as well as allergen plus DEP in saline in a randomized crossover design. Challenges were separated by at least 6 wk. **Time to analysis:** 10 min, 24 h, and 72 h post-challenge.	Subjects who were GSTM1 null or homozygous for GSTP1 I105 wild-type allele experienced significantly greater increase in nasal IgE and histamine with diesel plus allergen compared to subjects with functional GSTM1 or who were heterozygous for GSTP1 I/V(105).
Reference: Gong et al. (2004, 087964) **Subjects:** 13 older adults with COPD, 6 healthy older adults **Gender:** COPD: 5 M/8 F, Healthy: 2 M/4 F **Age:** COPD: avg 68 yr, Healthy: avg 73 yr	Fine CAPs (Los Angeles) **Particle Size:** 85% of mass between 0.1 and 2.5 µm **Concentration:** Mean: 194 µg/m^3, Range: 135-229 µg/m^3	Exposures to CAPs and filtered air (randomized crossover) for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wk. **Time to analysis:** Immediately following exposure as well as 4 and 22 h post-exposure.	No CAPs-induced respiratory symptoms observed in healthy older adults or older adults with COPD at 0, 4, or 22 h post-exposure. Exposure to CAPs did not significantly affect FVC or FEV_1. CAPs exposure caused a decrease in arterial oxygen saturation immediately following exposure which was more pronounced in healthy older adults than in older adults with COPD. Exposure to CAPs was not observed to affect the levels of white blood cells, columnar epithelial cells, IL-6, or IL-8 in induced sputum.
Reference: Gong et al. (2004, 055628) **Subjects:** 12 adult asthmatics, 4 healthy adults **Gender:** Asthmatic: 4 M/8 F, Healthy: 2 M/2 F **Age:** Asthmatic: avg 38 yr, Healthy: avg 32 yr	Coarse CAPs (Los Angeles) **Particle Size:** 80% of mass between 2.5 and 10 µm, 20% of mass <2.5 µm **Concentration:** Mean: 157 µg/m^3; Range: 56-218 µg/m^3	Exposures to CAPs and filtered air (randomized crossover) for 2 h with intermittent light exercise (four 15-min periods). Exposures were separated by at least 2 wk. **Time to analysis:** Immediately following exposure as well as 4 and 22 h post-exposure.	No effect of CAPs exposure on spirometry or arterial oxygen saturation was observed 0, 4, or 22 h post-exposure. No respiratory symptoms reported 0-22 h post-exposure in either healthy or asthmatic adults. Sputum cell counts at 22 h post-exposure did not differ between CAPs and filtered air.

Reference	Pollutant	Exposure	Findings
Reference: Gong et al. (2005, 087921) **Subjects:** 18 older adults with COPD, 6 healthy older adults **Gender:** COPD: 9 M/9 F, Healthy: 2 M/4 F **Age:** COPD: avg 72 yr, Healthy: avg 68 yr	Fine CAPs (Los Angeles) **Concentration:** CAPs: 200 µg/m^3; NO_2: 0.4 ppm	Each subject was exposed to CAPs, NO_2, CAPs + NO_2, and filtered air for 2 h with intermittent exercise. Exposure order was not fully counterbalanced as NO_2 exposures were conducted after the majority of the CAPs and filtered air exposures had been completed. Exposures were separated by at least 2 wk. **Time to analysis:** Immediately following exposure as well as 4 and 22 h post-exposure.	Exposure to CAPs was observed to decrease maximal mid-expiratory flow and arterial oxygen saturation relative to filtered air 4-22 h post-exposure. This response was more pronounced in healthy older adults than in older adults with COPD. Concomitant exposure to NO_2 did not enhance the response. No other respiratory responses (symptoms, spirometry, sputum cell counts) were affected by exposure to CAPs.
Reference: Gong et al. (2008, 156483) **Subjects:** 14 adult asthmatics, 17 healthy adults **Gender:** Asthmatics: 9 M/5 F, Healthy: 5 M/12 F **Age:** Asthmatics: 34 ± 12 yr, Healthy:24 ± 8 yr	Ultrafine CAPs (Los Angeles) **Particle Number/Count:** 145,000/cm^3, Range 39,000-312,000/cm^3 **Concentration:** Mean: 100 µg/m^3, Range: 13-277 µg/m^3	Subjects exposed for 2 h during intermittent exercise (15-min periods) to both CAPs and filtered air in random order. The first 7 subjects underwent whole body exposure, while the remaining subjects were exposed through a facemask. Facemask exposures had higher particle counts but lower particle mass than whole body exposures. Exposures were separated by at least 2 wk. **Time to analysis:** Immediately following exposure as well as 4 and 22 h post-exposure.	No significant differences in respiratory symptoms observed between filtered air and ultrafine CAPs exposures. Individuals exposed to higher particle counts tended to experience greater symptoms with CAPs than with filtered air. An ultrafine CAPs-induced decrease in arterial oxygen saturation (0.5%) was observed at 0, 4, and 22 h post-exposure. A decrease in FEV_1 (2%) was also observed 22 h post-exposure relative to filtered air. Responses were not significantly different between healthy and asthmatic adults. CAPs exposure was not observed to affect total sputum cell counts or cytokine levels. There were no differences in response observed between facemask and whole body exposures.
Reference: Graff et al. (2009, 191981) **Subjects:** 14 healthy adults **Gender:** 8 M/6 F **Age:** 20-34 yr	Coarse CAPs (Chapel Hill, NC) **Concentration:** 89 ± 49.5 µg/m^3 (estimated inhaled dose ≈ 67% of measured particle mass)	Subjects exposed for 2 h with intermittent exercise (15-min periods) to coarse CAPs and filtered air in a randomized crossover design. Exposures were separated by at least 2 mos. **Time to analysis:** 0-1 and 20 h post-exposure.	Pulmonary function (FVC, FEV_1, and carbon monoxide diffusing capacity) was not affected by exposure to coarse CAPs either immediately following exposure or 20 h post-exposure. A significant increase in percent PMNs (10.7% increase per 10 µg/m^3 coarse CAPs) was observed in BAL fluid 20 h post-exposure. Percent monocytes in BL fluid were slightly decreased at 20 h post-exposure (2.0% decrease per 10 µg/m^3 CAPs; p = 0.05). Total protein in BAL fluid was also observed to decrease following CAPs exposure (1.8% decrease per 10 µg/m^3 CAPs). Markers of inflammation in BAL and BL fluids including IL-6, IL-8, and PGE2 were not affected by exposure to coarse CAPs.
Reference: Huang et al. (2003, 087377) **Subjects:** 38 healthy adults **Gender:** 36 M/2 F **Age:** Avg 26.2 ± 0.7 yr	Fine CAPs (Chapel Hill, NC) **Concentration:** 23.1-311.1 µg/m^3	Subjects exposed to CAPs (n = 30) or filtered air (n = 8) for 2 h with intermittent exercise (subjects did not serve as their own controls). Component data of CAPs was available for 37 of the 38 subjects. **Time to analysis:** 18 h after exposure.	The increase in bronchoalveolar lavage fluid neutrophils observed by Ghio et al. (2000, 012140) following exposure to fine CAPs was shown to be associated with iron, selenium, and sulfate content of the CAPs.
Reference: Kongerud et al. (2006, 156656) **Subjects:** 17 asthmatic adults, 46 healthy adults **Gender:** Asthmatics- 6 M/11 F, Healthy- 24 M/22 F **Age:** Asthmatics: avg 23 yr, Healthy: avg 26 yr	DEP NIST 1650, heavy duty diesel engine **Concentration:** Untreated and treated with 0.1 ppm O_3 (48 h); 300 µg per nostril	DEP (with and without O_3 pre-treatment) were intranasally instilled, using the saline vehicle as control. Subjects did not serve as their own controls (not a crossover design). **Time to analysis:** 4 and 96 h post-instillation.	Exposure to DEP was not observed to alter markers of inflammation in nasal lavage fluid (e.g., cell counts, IL-8, IL-6) at 4 or 96 h post-instillation.
Reference: Larsson et al. (2007, 091375) **Subjects:** 16 healthy adults **Gender:** 10 M/6 F **Age:** 19-59 yr	Traffic particles (road tunnel) **Particle Size:** $PM_{2.5}$, PM_{10}; $PM_{2.5}$ mass constituted ~36% of PM_{10} mass **Particle Number/Count:** 20-1,000 nm: 1.1 × 10^5/cm^3, < 100 nm: 0.85 × 10^5/cm^3 **Concentration:** $PM_{2.5}$-46-81 µg/m^3; PM_{10}-130-206 µg/m^3	Exposures were conducted for 2 h with intermittent exercise in a room adjacent to a busy road tunnel. Study used a randomized crossover design with each subject also exposed to normal air (control). Exposures were separated by 3-10wks. No exposures to filtered air were conducted. Other traffic emissions measured: NO (874 µg/m^3), NO_2 (230 µg/m^3), CO (5.8 µg/m^3 reported, likely 5.8 mg/m^3). **Time to analysis:** 14 h post-exposure.	An increase in bronchoalveolar lavage fluid cell number, lymphocytes, and alveolar macrophages were observed 14 h after road tunnel exposure relative to control. Traffic particulate exposure was not shown to effect cytokine or adhesion molecule expression in bronchial tissues. Respiratory symptoms were reported to increase during exposure to road tunnel air relative to pre-exposure symptom ratings. Exposure to road tunnel air was not shown to affect lung function.

Reference	Pollutant	Exposure	Findings
Reference: Mudway et al. (2004, 180208) **Subjects:** 25 healthy adults **Gender:** 16 M/9 F **Age:** 19-42 yr	DE Idling 1991 Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) **Concentration:** PM_{10} 100 µg/m^3	Subjects exposed to DE and filtered air for 2 h with intermittent exercise (15-min periods) in a randomized crossover design. Exposures were separated by at least 3 wk. Other diesel emissions measured: NO_2 (0.2 ppm), NO (0.6 ppm), CO (1.7 ppm), total hydrocarbons (1.4 ppm), formaldehyde (43.5 µg/m^3). **Time to analysis:** 1 h after the start of exposure, immediately following exposure, and 6 h post-exposure.	DE caused mild throat irritation in some subjects and a significant increase in airways resistance (Raw) during or immediately following exposure. No changes in FEV_1 or FVC were observed following exposure to diesel. Neutrophil numbers in the bronchial airways tended to increase following exposure to DE; however, this increase was highly variable between subjects and did not reach statistical significance. Exposure to DE did not affect levels of SOD or malondialdehyde in the airways. An increase in levels of ascorbate and GSH in nasal lavage fluid was observed 6 h following exposure to DE.
Reference: Pietropaoli et al. (2004, 156025) **Subjects:** 16 asthmatic adults, 40 healthy adults **Gender:** Asthmatic: 8 M/8 F, Healthy: 20 M/20 F **Age:** 18-40 yr	Ultrafine EC **Particle Size:** CMD ~25 nm **Particle Number/Count:** 10 µg/m^3: ~2.0 × 10^6/cm^3; 25 µg/m^3: ~7.0 × 10^6/cm^3; 50 µg/m^3: ~10.8 × 10^6/cm^3 **Concentration:** 10, 25, and 50 µg/m^3	Study conducted using a randomized crossover design with 2-h exposures. Asthmatics (n = 16) exposed to filtered air and 10 µg/m^3. 12 healthy adults exposed to filtered air and 10 µg/m^3 at rest; 12 healthy adults exposed to filtered air, 10 and 25 µg/m^3 with intermittent exercise; 16 healthy adults exposed to filtered air and 50 µg/m^3 with intermittent exercise. Exposures were conducted via mouthpiece. **Time to analysis:** Immediately following exposure as well as 3.5, 21, and 45 h post-exposure.	No PM-induced changes in eNO or cell counts, IL-6, or IL-8 in induced sputum were observed in any of the protocols 21 h following exposure. Ultrafine carbon was not observed to increase respiratory symptoms in any of the study protocols. Healthy adults experienced an ultrafine PM-induced reduction in maximal mid-expiratory flow and CO diffusing capacity relative to filtered air 21 h following exposure.
Reference: Pourazar et al. (2005, 088305) **Subjects:** 15 healthy adults **Gender:** 11 M/4 F **Age:** 21-28 yr	DE Idling Volvo diesel engine **Particle Number/Count:** 4.3 × 10^6/cm^3 **Concentration:** PM_{10} 300 µg/m^3	Subjects exposed to DE and filtered air for 1 h with intermittent exercise (randomized crossover study design). Other diesel emissions measured: NO_2 (1.6 ppm), NO (4.5 ppm), CO (7.5 ppm), total hydrocarbons (4.3 ppm), formaldehyde (0.26 mg/m^3). **Time to analysis:** 6 h post-exposure.	Exposure to DE significantly increased nuclear translocation of NF-κB, AP-1, phosphorylated p38, and phosphorylated JNK in bronchial epithelium 6 h post-exposure.

Exposure to DE observed to enhance epidermal growth factor receptor (EGFR) expression in bronchial epithelium 6 h post-exposure.
Reference: Riechelmann et al. (2004, 180120) **Subjects:** 30 healthy adults **Gender:** 11 M/19 F **Age:** 22-32 yr	Urban dust NIST SRM 1649a **Concentration:** 150, 500 µg/m^3	Subjects exposed to both concentrations of urban dust (nose only exposure system) as well as filtered air for 3h at rest in a randomized crossover design. Exposures were separated by at least 1 wk. **Time to analysis:** 30 min, 8 h, and 24 h post-exposure.	An increase in nasal secretion (nasal cytology) of IL-6 and IL-8 were observed 24 h after exposure to 500 µg/m^3 urban dust.
Reference: Samet et al. (2007, 156940) **Subjects:** Ultrafine CAPs: 20 healthy adults, Coarse CAPs: 14 healthy adults **Gender:** Ultrafine CAPs: 11 M/9 F, Coarse CAPs: 8 M/6 F **Age:** 18-35 yr	CAPs (Chapel Hill, NC) **Particle Size:** Ultrafine: 0.049 ± 0.009 µm, Coarse: 3.59 ± 0.58 µm **Concentration:** Ultrafine: 47.0 ± 20.2 µg/m^3, Coarse: 89.0 ± 49.5 µg/m^3	Preliminary report comparing effects of controlled exposures to coarse, fine, and ultrafine CAPs among healthy adults (3 separate studies). A randomized crossover design was used in evaluating effects of coarse CAPs (n=14) and ultrafine CAPs (n=20) relative to filtered air following of 2-h exposures with intermittent exercise. Results compared with previous study of controlled exposure to fine CAPs (Chapel Hill, NC) where subjects did not serve as their own controls (Ghio et al., 2000, 012140) **Time to analysis:** 0-20 h post-exposure.	As was shown with fine CAPs, exposure to coarse CAPs increased the percentage of neutrophils in bronchoalveolar lavage fluid 20 h following exposure. Unlike fine CAPs, coarse CAPs did not increase the percent of monocytes in bronchoalveolar lavage fluid. Ultrafine CAPs were not shown to affect any markers of pulmonary inflammation in bronchoalveolar lavage fluid 18 h after exposure. No CAPs-induced changes in lung function were observed.
Reference: Samet et al. (2009, 191913) **Subjects:** 19 healthy adults **Gender:** 10 M/9 F **Age:** 18-35 yr	Ultrafine CAPs (Chapel Hill, NC) **Particle Size:** < 0.16 µm **Particle Number/Count:** 120,662 ± 48,232 particles/cm^3 **Concentration:** 49.8 ± 20 µg/m^3	Subjects exposed for 2 h with intermittent 15 periods of exercise to UF CAPs and filtered air using a randomized crossover study design. **Time to analysis:** Immediately following exposure and 1 and 18 h post-exposure.	No effect of UF CAPs observed on pulmonary function immediately following exposure or 18 h post-exposure. IL-8 in BAL fluid was observed to increase with UF CAPs 18 h post-exposure. UF CAPs was not shown to alter any other inflammatory markers in BAL fluid.

Reference	Pollutant	Exposure	Findings
Reference: Schaumann et al. (2004, 087966) **Subjects:** 12 healthy adults **Gender:** 4 M/8 F **Age:** Avg 27 ± 2.5 yr	Fine PM Collected (filter) from industrialized and non-industrialized areas in Germany **Concentration:** 100 µg per subject	Bronchoscopic instillation of particles collected from both areas was conducted in contralateral lung segments for each subject. **Time to analysis:** 24 h post-instillation.	Particles collected from the industrialized area (transition metal-rich) increased the percentage of monocytes and oxidant radical generation in bronchoalveolar lavage fluid 24 h after exposure compared with PM containing less metal.
Reference: Stenfors et al. (2004, 157009) **Subjects:** 15 asthmatic adults, 25 healthy adults **Gender:** Asthmatic: 10 M/5 F, Healthy: 16 M/9 F **Age:** Asthmatic: 22-52 yr, Healthy:19-42 yr	DE Volvo diesel engine **Concentration:** PM_{10} 108 µg/m^3	Subjects were exposed for 2 h with intermittent exercise to DE and filtered air using a randomized crossover study design. Other diesel emissions measured: NO_2 (0.7 ppm). **Time to analysis:** 1 h after the start of exposure, immediately following exposure, and 6 h post-exposure.	DE was observed to increase neutrophilia and IL-8 in bronchial lavage fluid among healthy subjects 6 h after exposure. Among asthmatic subjects, exposure to DE did not cause an increase in inflammatory markers. No diesel-induced change in pulmonary function was observed during or immediately following exposure.
Reference: Tunnicliffe et al. (2003, 088744) **Subjects:** 12 asthmatic adults, 12 healthy adults **Gender:** Asthmatics: 7 M/5 F, Healthy: 5 M/7 F **Age:** Asthmatics: avg 35.7 yr, Healthy: avg 34.5 yr	Aerosols of ammonium bisulfate and sulfuric acid **Particle Size:** MMD 0.3 µm **Concentration:** 200, 2,000 µg/m^3	Subjects were exposed for 1 h at rest to ammonium bisulfate (low and high concentrations), sulfuric acid (low and high concentrations) and filtered air in a randomized crossover design. Exposures were separated by at least 2 wk and were conducted using a head dome exposure system. **Time to analysis:** Immediately following exposure as well as 5.5-6 h post-exposure.	Neither ammonium bisulfate nor aerosolized sulfuric acid were observed to affect lung function or respiratory systems following exposures to 200 or 2,000 µg/m^3 among healthy or asthmatic adults. Exposures to ammonium bisulfate at both concentrations resulted in a significant increase in eNO in the asthmatic subjects.

Table C- 3. Central nervous system effects.

Reference	Pollutant	Exposure	Findings
Reference: Cruts et al. (2008, 156374) **Subjects:** 10 healthy adults **Gender:** M **Age:** 18-39 yr	DE Idling Volvo diesel engine (TD45, 4.5 L, 4 cylinders, 680 rpm) **Particle Number/Count:** 1.2 × 10^6/cm^3 **Concentration:** 300 µg/m^3	Subjects were exposed to DE and filtered air for 1 h at rest in a randomized crossover study design. Exposures were separated by 2-4 days. Other diesel emissions measured: NO_2 (1.6 ppm), NO (4.5 ppm), CO (7.5 ppm), total hydrocarbons (4.3 ppm). **Time to analysis:** From onset of exposure until 1 h post-exposure.	Exposure to DE was observed to significantly increase the median power frequency (MPF) in the frontal cortex during exposure, as well as in the hour following the completion of the exposure.

Annex D. Toxicological Studies

Table D-1. Cardiovascular effects.

Study	Pollutant	Exposure	Effects
Reference: Anselme et al. (2007, 097084) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** Adult **Weight**: 200-225g	**DE:** monocylinder Diesel engine using Euro 4 ELF 85A reference gasoline **Particle Size:** DE: 10-650 nm (85 nm mean mobility diameter)	**Route:** Whole-body Inhalation **Dose/Concentration:** DE: 0.5 mg/m^3; Other emissions measured: non-methane hydrocarbons (7.7 ppm), NO_2 (1.1 ppm), CO (4.3 ppm) **Time to Analysis:** Experiments started 3 mo after L coronary artery ligation. ECG started at t0 and the DE exposure at t30 min for a 3-h period; ventricular premature beats (VPBs) and RMSSD calculated every 30 min during clean room air exhaust and PE periods. Early (t210-300 min) and late (t480-540 min) PE were analyzed.	Immediate decrease in RMSSD was observed in both healthy and CHF rats PE. Immediate increase in VPBs observed in CHF rats only; which lasted 4-5 h after exposure ceased. Whereas HRV progressively returned to baseline values within 2.5 h post-exposure (PE), the proarrhythmic effect persisted as late as 5 h PE termination in CHF rats
Reference: Bagate et al. (2004, 055638) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 13-15 wk	**LPS and EHC-93 (PM):** Urban Air collected at the Health Effects Institute Ottawa, Canada **Particle Size:** EHC-93: 0.8-0.4 µm (mean) (range: <3 µm)	**Route:** IT Instillation **Dose/Concentration:** PM: 10 mg/kg; LPS- 350 EU/animal **Time to Analysis:** Sacrificed 4 or 24 h post-instillation	PM and LPS elicited a significant increase in receptor-dependent vasorelaxation of the aorta compared to saline-instilled rats.
Reference: Bagate et al. (2004, 055638) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 13-15 wk	EHC-93 (PM), CB-V or CB-Fe, LPS **Particle Size:** EHC-93: 0.8-0.4 µm (mean) (range: <3 µm)	**Route:** Aortic Suspension Fluid **Dose/Concentration:** Cumulative concentrations of EHC-93, CB-V and CB-Fe (10, 25, 50, 75, 100 µg/mL) CB 1.5-2.0 nm (mean) (range <5 µm) **Time to Analysis:** Immediately post-exposure of aortic rings to cumulative concentrations of EHC-93, CB-V, CB-Fe and LPS.	CB-V particles induced more relaxation than CB-Fe particles or EHC-93 in a dose-dependent manner. PM and LPS had an acute transient effect on the receptor dependent vasorelaxation. PM and LPS attenuated ACh-elicited vasocontraction in denuded aortic rings (DARs).

Study	Pollutant	Exposure	Effects
Reference: Bagate et al. (2004, 055638) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 13-15 wk	EHC-93 (PM): Urban Air collected at the Health Effects Institute Ottawa, Canada. EHC-93 filtrate (PMF) Zn^{2+} and Cu^{2+} particles (10,000 and 845 µg PM respectively) **Particle Size:** PM: 4.6 µm (GSD = 3.2)	**Route:** In Vitro **Dose/Concentration:** PM Suspensions: 10-100 µg/mL; $CuSO_4$/$ZnSO_4$ 1-100 µmol; Phe 2 µm; arbacol: 10 µm **Time to Analysis:** Measured immediately after maximum response for each cumulative dose was achieved.	**PM-Induced Contraction:** No effect of suspension or filtrate seen on resting tension of aorta and SMRA. **PM- and Metal-Induced Vasorelaxation:** Cumulative concentrations (10-100 µg/mL) of PM suspension and its water soluble components (PMF) elicited dose-dependent relaxation in aorta. Relaxation induced by particle suspension was higher than relaxation induced by free filtrate. The difference was significant at 100 µg/mL. In SMRA, vasorelaxation similar to aorta's was observed, and the activity of the particle suspension was stronger than the filtrate, with the difference being significant starting at 30 µg/mL. Both Zn^{2+} and Cu^{2+} in sulfate salts (10-100 µmol) induced relaxation in pre-contracted aortic rings, with Cu^{2+} having a greater effect than Zn^{2+} at the same concentration. Ions didn't affect ACh relaxation. **Effect of PM on α-Adrenergic Contraction:** Phenylephrine-induced dose-response contraction, starting at 1µM with max at 100 µmol. Pre-treatment of SMRA did not change the phenylephrine-induced contraction.
Reference: Bagate et al. (2006, 097608) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto and SH **Age:** 13-15 wk	EHC-93 (PM) EHC-93 (Filtrate) Cu^{2+} and Zn^{2+} solutions **Particle Size:** PM: 4.6 µm (GSD = 3.2)	**Route:** In Vitro **Dose/Concentration:** PM and PMF Suspensions: 10-100 µg/mL; $CuSO_4$ or $ZnSO_4$:10-100 µmol; Phenylephrine: 2 µm; Carbacol: 10 µm **Time to Analysis:** Responses evaluated at maximum of each dose-response.	PM and its soluble components elicited endothelium-independent vasodilation in rat aorta rings. This response is a result of the activation of sGC since its inhibition by NS2028 practically eliminated relaxation. PM suspensions stimulated cGMP production in purified isolated sGC. Neither receptor nor their signaling pathways played a significant role in the direct relaxation by PM or metals. Vasodilation responses were significantly higher in SH than WKY control rats.
Reference: Bagate et al. (2006, 096157) **Species:** Rat **Gender:** Male **Strain:** SH/NHsd **Age:** 11-12 wk **Weight:** 250-350 g	EHC-93 (PM): Urban Air collected at the Health Effects Institute Ottawa, Canada. EHC-93 (Filtrate), Zinc (in PM), LPS **Particle Size:** PM: 4.6 µm (GSD = 3.2)	**Route:** IT Instillation **Dose/Concentration:** PM: 10 mg/kg; LPS: 350 EU/animal (0.5 mL) **Time to Analysis:** 4 h post-exposure	**Effect of Pretreatment on Baseline Parameters of Isolated Perfused Heart:** After PM exposure a slight increase of baseline coronary flow (CF) and heart rate (HR) was noted. In contrast, a significant decrease of left developing ventricular pressure (LDVP) was observed in SH. LPS also elicited a non-significant decrease in LVDP. **Effect of Pretreatment and Ischemia on Cardiac Function:** When SH rats were pretreated with PM or LPS the isolated heart had a reduced ability to recover to baseline levels after occlusion, in comparison with saline treated rats. After occlusion was released CF went back to baseline values. Saline and LPS treated rats, showed a gradual decrease in CF noted during the reperfusion period. Isolated hearts from PM-exposed SH showed a complete restoration of CF and no gradual decrease. The increase of Zn2+ elicited a rapid decrease of LDVP and HR. The impairment of cardiac function measured by LDVP and HR started immediately upon Zn2+ infusion and remained the same during the perfusion period (no Zn2+ was present in the perfusate).

Reference: Bartoli et al. (2009, 156256) **Species:** Dog **Gender:** Female **Strain:** Mixed breed **Age:** 2-12 yr **Weight:** Average: 15.7 kg, Range: 13.6-18.2 kg	CAPs (Boston; Harvard Ambient Particle Concentrator) **Particle Size:** Diameter: 0.15-2.5 µm	**Route:** Permanent Tracheostomy **Dose/Concentration:** Concentration range and mean: CAPs: 94.1-1557(358.1 ± 306.7) µg/m^3, BC: 1.3-32(7.5 ± 6.1) µg/m^3, Particle count: 3000-69300(18230 ± 13.151) particles/cm^3 **Time to Analysis:** Preanesthetized. Tracheostomy. 5 h exposures separated by minimum 1wk. Prazosin administered in 8 of 13 dogs 30-60 min before exposure. 55 exposure days.	CAPs significantly increased SBP, DBP, mean arterial pressure, HR and rate-pressure product. Prazosin (α-adrenergic antagonist) decreased these CAPs-induced effects. CAPs mass, BC, particle number concentrations were positively and significantly associated with each of the cardiovascular parameters except for pulse pressure.
Reference: Bartoli et al. (2009, 179904) **Species:** Dog **Gender:** Female **Strain:** Mixed breed **Age:** Adult **Weight:** 14-18 kg	CAPs (Boston; Harvard Ambient Particle Concentration) **Particle Size:** Diameter: ≤2.5 µm	**Route:** Permanent Tracheostomy **Dose/Concentration:** Concentration range and mean: CAPs: 94.1-1556.8 (349 ± 282.6) µg/m^3, BC: 1.3-32 (7.5 ± 5.6) µg/m^3, Particle number: 3000-69300 (20381 ± 13075) particles/cm^3 **Time to Analysis:** Tracheostomy. Minimum 3 wk recovery. Acclimatized. Exposed 5 h. 2 5 min occlusions of LAD coronary artery separated by 20 min rest. Exposure days separated by 1wk minimum.	During coronary artery occlusion, CAPs exposure reduced myocardial blood flow and increased coronary vascular resistance, SBP and DBP. CAPs effects were greater in ischemic tissue than nonischemic. Increases in CAPs mass, particle number and BC concentrations were significantly associated with decreased myocardial blood flow and increased coronary vascular resistance.
Reference: Campen et al. (2005, 083977) **Species:** Mouse **Gender:** Male **Strain:** C57BL/6J and Apo E$^{-/-}$ **Age:** 10-12 wk	High Whole DE (HWDE); Low Whole DE (LWDE); High PM Filtered (HPMF); Low PM Filtered (LPMF) **Particle Size:** NR	**Route:** Whole-body Inhalation and Ex-vivo Exposures (isolated, pressurized septal coronary arteries) **Dose/Concentration:** HWDE: PM = 3.6 mg/m^3; NO_X = 102 ppm LWDE: PM = 0.512 mg/m^3; NO_X = 19 ppm; PM = 0.770 mg/m^3; NO_X = 105 ppm LPMF: PM = 0.006 mg/m^3; NO_X = 26 ppm **Time to Analysis:** Whole-body Exposures: DE or PFDE for 6 h/day for 3 days, euthanized at the end of last exposure. **Coronary Vessels Exposure:** PSS bubbled with DE to expose coronary vessels to the soluble contents of DE. Analysis occurred immediately post exposure.	**Whole-body Exposure on ApoE$^{-/-}$:** During DE exposure, ApoE$^{-/-}$ mice HR consistently decreased during high concentration exposures, compared to the C57BL/6J strain. **Coronary Vascular Effects on ApoE$^{-/-}$:** DE had no significant effects on the resting myogenic tone of isolated septal coronary arteries. Control coronary arteries showed constrictive responses to ET-1 and dilatory responses to SNP. DE exposed PSS vessels responses to ET-1 enhanced compared to control. SNP-induced dilation blunted in vessels resting in diesel-exposed saline.

Reference: Cascio et al. (1987, 007583) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6-10 wk	UFPM: Ultra fine PM, EPA Chapel Hill, NC **Particle Size:** <0.1 µm	**Route:** IT Instillation **Dose/Concentration:** 100 µg in 100 µl **Time to Analysis:** 24 h post-exposure (single exposure)	UFPM exposure double the size of myocardial infarction attendant to an episode of ischemia and reperfusion while increasing post ischemic oxidant stress. UFPM alters endothelium-dependent/independent regulation of systemic vascular tone; increases platelet number, plasma fibrinogen, and soluble P-selectin levels; reduces bleeding time.
Reference: Chang et al. (2007, 155720) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 60 days	UfCB: Ultra fine carbon black Ferric sulfate $Fe_2(SO_4)_3$ Nickel sulfate $NiSO_4$ **Particle Size:** UfCB	**Route:** IT Instillation **Dose/Concentration:** UfCB: 415 and 830 µg Ferric Sulfate: 105 and 210 µg Nickel Sulfate: 263 and 526 µg Combined UfCB and ferric sulfate: 830 µg UfCB + 105 µg ferric sulfate Combined UfCB with Nickel Sulfate: 830 µg UfCB + 263 µg Nickel Sulfate **Time to Analysis:** Single dose, radiotelemetry readings recorded for 72 h post- exposure.	Both high/low-dose UfCB decreased ANN (normal-to-normal intervals) slightly around the 30th h, concurrent increases of LnSDNN. LnRMSSD returned to baseline levels after small initial increases. Minor effects observed after low-dose Fe and Ni instillation; biphasic changes occurred after high-dose instillations. Combined exposures of UfCB and either Fe or Ni resulted in HRV trends different from values estimated from individual-component effects.
Reference: Chang et al. (2007, 155720) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 10 wk	CAPs: collected during a dust storm from Chung-Li, Taipei **Particle Size:** $PM_{2.5}$	**Route:** Nose-only Inhalation **Dose/Concentration:** 315.55 µg/m^3 **Time to Analysis:** 6 h	A linear mixed-effects model revealed sigmoid increases in HR and a sigmoid decrease of QAI during exposure, after an initial incubation period.
Reference: Chang et al. (2004, 055637) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 60 days	CAPs collected in Chung-Li, Taipei (spring and summer periods) **Particle Size:** $PM_{2.5}$	**Route:** Nose-only Inhalation **Dose/Concentration:** Spring exposure: 202.0 ± 68,8 µg/m^3; Mean number concentration: 2.30 × 10^5 particles/cm^3 (range: 7.12 ×10^3 - 8.26 ×10^5) Summer exposure: 141.0 ± 54.9 µg/m^3; Mean number concentration: 2.78 ×10^5 particles/cm^3 (range: 7.76 ×10^3 - 8.87 × 10^5) **Time to Analysis:** 4 days of spring exposure and days of summer exposure for 5 h each exposure. Parameters measured throughout duration of exposures.	During spring exposures, the maximum increase of heart rate (HR) and blood pressure (BP) were 51.6 bpm and 8.5 mmHg respectively. The maximum decrease of QAI (measures cardiac contractility) noted at the same time was 1.6 ms. Similar pattern was observed during summer exposure, however., the responses were less prominent.
Reference: Chang, et al. (2005, 097776) **Species:** Rat **Gender:** Male **Strain:** SH **Weight**: 200 g	CAPs collected in Chung-Li, Taipei **Particle Size:** $PM_{2.5}$ (0.1-2.5 µm)	**Route:** Nose-only Inhalation **Dose/Concentration:** 202.0 ± 68.8 µg/m^3 **Time to Analysis:** 5 h/days for 4 days	During the inhalation stage, crude effects of both LnSDNN and LnRMSSD for exposure and control groups decreased from the baseline values. Immediately after the experiments, both LnSDNN and LNRMSSD decreased due to stresses produced by release from the exposure system, then returned to the baseline values.
Reference: Chauhan et al. (2005, 155722) **Tumor Cell Line:** A549 derived from alveolar type II epithelial cells	SRM-1879 (SiO_2) and SRM-154b (TiO_2) from the NIST EHC-93 from Ontario, Canada (EHCsol, EHCinsol) **Particle Size:** EHC-93 median physical diameter: 0.4 µm; TiO_2 and SiO_2 particle size distribution: 0.3-0.6 µm	**Route:** Cell Culture **Dose/Concentration:** 0, 1, 4, and 8 mg EHC total equivalent per 5 mL **Time to Analysis:** Culture medium was removed from flasks and replaced w/ 5 mL of the particle suspension media. Plates were incubated for 24 h. After 24 h cell culture supernatants were collected and analyzed.	The decreased expression of preproET-1 in A549 cells suggests that epithelial cells may not be the source of higher pulmonary ET-1 spillover in the circulation measured in vivo in response to inhaled urban particles. However, higher levels ECE-1 in A549 post-exposure to particles suggests an increased ability to process bigET-1 into mature ET-1 peptide, while increased receptor expression implies responsiveness. The increased release of Il-8 and VEGF by epithelial cells in response to particles could possibly up regulate ET-1 production in the adjacent pulmonary capillary endothelial cells, with concomitant increased ET-1 spillover in the systemic circulation.

Reference: Chen et al. (2005, 087218) **Species:** Mouse **Strain:** C57 and ApoE$^{-/-}$	CAPs (NYU, NY) **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** 19.7 µg/m^3 average concentration over 5 mo (daily average exposure concentration was 110 µg/m^3) **Time to Analysis:** 6 h/days, 5 days/wk, for 5 mo. Parameters measured continuously throughout.	Significant decreasing patterns of HR, body temperature, and physical activity for ApoE$^{-/-}$ mice, with nonsignificant changes for C57 mice. SDNN and RMSSD in the late afternoon and overnight for ApoE$^{-/-}$ mice showed a gradual increase for the first 6 wk, a decline for about 12 more weeks, and a slight turn upward at the end of the study period. For C57 mice, there were no chronic effect changes in SDNN or RNSSD in the late afternoon, and a slight increase after 6 wk for the overnight period.
Reference: Chen and Nadziejkov(2005, 087219)**(Chen and Nadziejko, 2005, 087219)** **Species:** Mouse **Strain:** C57, ApoE$^{-/-}$ **Age:** 26-28 wk (C57), 39-41 wk (ApoE$^{-/-}$), and 18-20 wk (LDLr$^{-/-}$ [DK])	CAPs (NYU, NY) **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** Mean exposure concentration: 110 µg/m^3 **Time to Analysis:** 6 h/days, 5 days/wk for up to 5mo. Sacrificed 3-6 days after last exposure.	All DK mice developed extensive lesions in the aortic sinus regions. In male DK mice, the lesion areas appeared to be enhanced by CAPs exposure. Plaque cellularity was increased, but there were no CAPs-associated changes in the lipid content. ApoE$^{-/-}$ and DK mice showed prominent areas of severe atherosclerosis. Quantitative measurements showed that CAPs increased the percentage of aortic intimal surface covered by grossly discernible atherosclerotic lesion.
Reference: Corey LM et al. (2006, 156366) **(2006, 156366)**(Corey et al., 2006, 156366) **Species:** Mouse **Gender:** Male **Strain:** ApoE$^{-/-}$ **Age:** 11-12 mo **Weight**: 32.84 g (avg)	PM collected November - March between 1996-1999 (Seattle, WA) Silica (U.S. Silica Company, Berkeley Springs, WV) **Particle Size:** $PM_{2.5}$	**Route:** Nasal Instillation **Dose/Concentration:** PM: 1.5 mg/kg; Saline: 50 ul; Silica: Min-u-Sil 5 in 50 µl saline **Time to Analysis:** Mice monitored for 1 day baseline prior to and for 4 days following exposure.	After an initial increase in both HR and activity in all groups, there was delayed bradycardia with no change in activity of the animals in the PM and silica exposed groups. In addition, with PM and silica exposure, there was a decrease in HRV parameters.
Reference: Cozzi et al. (2006, 091380) **Species:** Mouse **Strain:** ICR **Age:** 6-10 wk	Ultrafine PM (collected continuously over 7-day periods in Oct 2002 in Chapel Hill, NC) **Particle Size:** <150 nm	**Route:** IT Instillation **Dose/Concentration:** 100 µg of PM in vehicle **Time to Analysis:** 24 h post-exposure	**Ischemia-Reperfusion:** PM exposure doubled the relative size of myocardial infarction compared with the vehicle control. No difference was observed in the percentage of the vehicle at the risk of ischemia. PM exposure increased the level of oxidative stress in the myocardium after I-R. The density of neutrophils in the reperfused myocardium was increased by PM exposure, but differences in the numbers of blood leukocytes, expression of adhesion molecules on circulating neutrophils, and activation state of circulating neutrophils, 24 h after PM exposure, could not be correlated to the increase I-R injury observed. **Isolated Aortas:** Aortas isolated from PM-exposed animals exhibited a reduced endothelium-dependent relaxation response to ACh.
Reference: Dvonch JT et al. (2004, 055741) **Species:** Rat **Gender:** Male **Strain:** Brown Norway	CAPs, Detroit, MI **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** Average concentration 354 µg/m^3 **Time to Analysis:** 8 h/days for 3 consecutive days; plasma samples collected 24 h post-exposure.	Plasma concentrations of asymmetric dimethylarginine (ADMA) were significantly elevated in rats exposed to CAPs versus filtered air.

Study	Pollutant	Exposure	Effects
Reference: Elder et al. (2004, 055642) **Species:** Rat **Gender:** Male **Strain:** Fischer 344 and SH **Age:** 23 mo (Fischer); 11-14 mo (SH) **Weight:** NR	UFP - Ultrafine carbon particles; LPS (Sigma) **Particle Size:** UFP: 36 nm (median size)	**Route:** Whole-body inhalation; intraperitoneal injection (ip) for saline and LPS **Dose/Concentration:** Particles: 150 µg/m^3; LPS: 2 mg/kg bw **Time to Analysis:** Single 6-h exposure to particles. Sacrificed 24 h after ip LPS exposure.	**BAL Fluid Cells:** Neither inhaled UFP nor ip LPS cause a significant increase in BAL fluid total cells or the percentage of neutrophils in either rat strain. No significant exposure-related alteration in total protein concentration or the activities of LDH and b-glucuronidase. **Peripheral Blood:** In both rat strains ip LPS induced significant increase in the number and percentage of circulating PMNs. When combined with inhaled UFP, PMNs decreased, significantly for F-344 rats. Plasma fibrinogen increased with ip LPS in both rat strains with the magnitude of change greater in SH rats. UFP alone decreased plasma fibrinogen in SH rats. Combined UFP and LPS response was blunted, but significantly higher than controls. Hematocrit was not altered in either rat strain by any treatment. **TAT Complexes:** With all exposure groups averaged, plasma TAT complexes in SH rats were 6.5 times higher than in F-344 rats. LPS caused an overall increase in TAT complexes for F-344 rats that was further augmented by inhaled UFP. UFP alone decreased response. In SH rats, UFP alone significant increased response and LPS decreased response. **ROS in BAL Cells:** In F-344 rats both UFP and LPS have independent and significant effects on DCFD oxidation. Effects were in opposite directions; particles decreased ROS, LPS increased ROS.

Reference: Furuyama et al. (2006, 097056) **Species:** Rat **Cell Type:** Heart Micro vessel Endothelial (RHMVE) Cells	OE-DEP, OE-UFP (from Urawa, Saitama, Japan) OE = Organic Extracts **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 0, 5, 10, 25 µg/mL of OE-DEP or OE-UFP **Time to Analysis:** Exposed for 0, 6, 12, 24, or 36 h	The cell monolayer exposed to 10 µg/mL OE-UFP produced a larger amount of HO-1 than cells exposed to 10 µg/mL OE-UFP. OE-DEP and OE-UFP exposure reduced PAI-1 production by the cells but did not affect the production of thrombomodulin, tissue-type PA, or urokinase-type PA. Increased PAI-1 synthesis in response to treatment with 1 ng/mL TNF-α or 0.5ng/mL TGF-β1 was reduced by OE-DEP exposure. Suppression of PAI-1 production by OE-DEP exposure was mediated through oxidative stress and was independent of HO-1 activity.
Reference: Gerlofs-Nijland et al. (2009, 190353) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 12 wk **Weight:** 200-300 g	PM (Prague, Czech Republic; Duisburg, Germany; Barcelona, Spain) (Prague and Barcelona coarse PM organic extracts) **Particle Size:** Coarse: 2.5-10 µm, Fine: 0.2-2.5 µm	**Route:** IT Instillation **Dose/Concentration:** 7 mg /kg **Time to Analysis:** DTPA added to some PM samples preinstillation. Instilled with PM. Necropsy 24 h post-exposure.	Inflammation (LDH, protein, albumin), cytotoxicity (NAG, MPO, TNF-α), and fibrinogen were increased by PM, and were greatest in the coarse PM fraction. Metal-rich PM had greater inflammatory and cytotoxic effects, and increased fibrinogen and vWF and decreased ACE. PAH content influenced greater inflammation (including neutrophils), cytotoxicity, and fibrinogen. Generally, whole PM and coarse PM were more potent than organic extracts and fine PM, respectively.
Reference: Gerlofs-Nijland et al. (2007, 097840) **Species:** Rat **Gender:** Male **Strain:** SH/NHsd **Age:** 13 wk **Weight:** 250-350 g	PM samples collected from: 1. MOB high traffic density 2. HIA high traffic density 3. ROM high traffic density 4. DOR moderate traffic density 5 MGH low traffic density 6 LYC low traffic density **Particle Size:** Coarse: 2.5-10 µm; Fine: 0.1-2.5 µm	**Route:** IT Instillation **Dose/Concentration:** 3, 10 mg/kg **Time to Analysis:** 24 h	**Hematology:** Fibrinogen responses of SH rats increased significantly at the high dose of both fractions of all PM samples, except fine PM from DOR. **Location-Related Differences:** Coarse PM from LYC lowered fibrinogen values more than PM from location MOB, HIA, and MGH. Fine PM showed less differences among the various sites.
Reference: Gerlofs-Nijland et al. (2005, 088652) **Species:** Rat **Gender:** Male **Strain:** SH/NHsd **Age:** 11-12 wk **Weight:** 250-350 g	RTD: road tunnel dust (obtained from a Motorway tunnel in Hendrik-Ido-Ambacht, Netherlands) EHC-93 (Ottawa, Canada) **Particle Size:** Coarse: 2.5-10 µm; fine: 0.1-2.5 µm	**Route:** IT Instillation **Dose/Concentration:** 0.3, 1, 3, 10 mg/kg; EHC-93: 10 mg/kg **Time to Analysis:** 4, 24, 48 h	**Hematology:** No significant changes in plasma for bigET-1 or von Willebrand factor were observed. At the highest dose, fibrinogen levels significantly increased at 24 and 4 h for both PM types.
Reference: Ghelfi et al. (2008, 156468) **Species:** Rat **Strain:** SD **Age:** Adult	CAPs CPZ (Capsazepine) (Axxora LLC, San Diego, CA) **Particle Size:** $PM_{2.5}$	**Route:** CAPs: Whole-body Inhalation; CPZ: IP Injection or Aerosol **Dose/Concentration:** CAPs: mean mass concentration: 218 ± 23 µg/m^3; CPZ: 10 mg/kg (ip), 500 µmol (aerosol) **Time to Analysis:** Experiment 1: CPZ ip or 20 min aerosol pretreatment immediately prior to CAPs exposure. Single CAPs exposure for 5 h. Parameters measured immediately following exposure. Experiment 2: CPZ ip pretreatment prior to CAPs exposure. Exposed to CAPs for 5 h/day for 4 mo. Parameters measured throughout duration of experiment.	CPZ (ip or aerosol) decreased CAPs-induced chemiluminescence (CL), lipid thiobarbituric acid reactive substances (TBARS), and edema in the heart, indicating that blocking TRP receptors, systemically or locally, decreases heart CL. CAPs exposure led to significant decreases in HR and in the length of QT, RT, Pdur and Tpe intervals. These changes were observed immediately upon exposure, and were maintained throughout the 5-h period of CAPs inhalation. Changes in cardiac rhythm and ECG morphology were prevented by CPZ.

(2004, 054175) **Species:** Rat **Gender:** Male **Strain:** Wistar	ufCB (Printex 90 from Frankfurt, Germany) fCB (Huber 990 from UK) **Particle Size:** ufCB: 114 nm (MMAD); fCB: 268 nm (MMAD).	**Route:** Whole-body Inhalation **Dose/Concentration:** ufCB: 1.66 mg/m^3; fCB: 1.40 mg/m^3 **Time to Analysis:** Single exposure for 7 h. Sacrificed and samples taken at 0, 16, and 48 h post-exposure.	Exposure to ultrafine, but not fine, CB particles was also associated with significant increases in the total number of blood leukocytes. Plasma fibrinogen factor VIII and vWF were unaffected by particle treatments as was plasma Trolox equivalent antioxidant status.
Reference: Gilmour et al. (2005, 087410) **Species:** Human **Cell Types:** Primary Human Monocyte Derived Macrophages (MP); Human Umbilical Vein Endothelial Cells (HUVEC); A549 cells; 16HBE	PM_{10}: (Carbon Black from Degussa Ltd, Frankfurt, Germany) **Particle Size:** PM_{10}	**Route:** Cell Culture **Dose/Concentration:** PM_{10}: 50 and 100 µg/mL **Time to Analysis:** 6 and 20 h	The culture media from MPs and 16HBE cells but not A549 cells, exposed to PM_{10} had an enhanced ability to cause clotting. H_2O_2 also increased clotting activity. Apoptosis was significantly increased in MPs exposed to PM_{10} and LPS as shown by annexin V binding. TF gene expression was enhanced in MPs exposed to PM_{10} and HUVEC tissue factor. tPA gene and protein expression were inhibited.
Reference: Gilmour et al. (2006, 156472) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 12-14 wk **Weight:** 280-340 g	Zinc Sulfate ($ZnSO_4$ in saline solution) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 131 µg/kg (2 µmol/kg) **Time to Analysis:** 1, 4, 24, 48 h	**Zinc levels in plasma and tissue:** At 1-24 h post-exposure, zinc plasma levels increased to nearly 20% above baseline. **mRNA expression:** Cardiac tissues demonstrated similar temporal increases in expressions of TF, PAI-1 and thrombomodulin mRNA, following pulmonary instillation of Zn. **Cardiac histopathology:** Mild and focal acute, myocardial lesions developed in a few Zn exposed rats. No changes in fibrin deposition or troponin disappearance were observed. At 24 and 48h PE to Zn, increases occurred in levels of systemic fibrinogen an the activated partial thromboplastin time.
Reference: Gong et al. (2007, 091155) **Species:** Mouse **Cell Type:** Human Microvascular Endothelial Cells (HMEC) **Strain:** C57BL/6J **Gender:** Male **Age:** 2 mo	Organic DEP extract: collected from exhaust in a 4JB1-type LD, 2.74 liter, 4-cylinder Isuzu diesel engine (provided by Masaru Sagai, Tsukuba, Japan) ox-PAPC: (provided by Judith Berliner, UCLA, CA) In vivo validation: Ultrafine (ufp) and fine (fp) particulate matter **Particle Size:** DEP <1 µm (diameter)	**Route:** Cell culture; In vivo validation via Whole-body inhalation **Dose/Concentration:** ox-PAPC: 10, 20, and 40 µg/mL; DEP: 5, 15, and 25 µg/mL; DEP (5 µg/mL)+ox-PAPC: 10 or 20 µg/mL In Vivo Validation: Ufp: 3.2 4×10^5/cm^3; fp: 2.7 $\times10^5$/cm^3 In vivo validation: Ufp: <0.18 µm; fp: <2.5 µm **Time to Analysis:** 4 h In vivo validation: Exposed to CAPs for 5 h/day, 3 days/wk for 8 wk. Sacrificed 24 h after last CAPs exposure.	Gene-expression profiling showed that both DEP extract and ox-PAPC co-regulated a large number of genes. Network analysis to identify co-expressed gene modules, led to the discovery of three modules that were highly enriched in genes that were differentially regulated by the stimuli. These modules were also enriched in synergistically co-regulated genes and pathways relevant to vascular inflammation. **In vivo validation:** Results were validated by demonstrating that hypercholesterolemic mice exposed to ambient ultrafine particles inhibited significant upregulation of the module genes in the liver.

Reference: Goto et al. (2004, 088100) **Species:** Rabbit **Gender:** Female **Strains:** New Zealand White **Age:** NR **Weight:** 2.3 kg	EHC-93 (Ottawa, ON,Canada) CC: Coilloidal Carbon (obtained from Hamburg, Germany) **Particle Size:** EHC-93: PM_{10}; CC: <1 µm	**Route:** Intrabronchial Instillation **Dose/Concentration:** AMs incubated with EHC-93 or CC: 0.6 ml/kg EHC-93 alone: 1 mL (500 µg/ mL) CC alone: 1mL (1% CC) **Time to Analysis:** WBC counts measured 4-168 h after BrdU injection. Sacrificed 7days post instillation.	**Lung Distribution of PM_{10}:** PM-containing AMs were distributed diffusely. PM-containing AMs were more prevalent in the PM exposed animals. There was no AM-containing particle difference between the CC-exposed and EHC-93-exposed groups. **Monocyte Release from Bone Marrow:** EHC exposure increased WBC and band cell counts from 12 h after instillation. Monocyte count was not affected. Labeled monocytes peaked more quickly after DEP exposure (12 vs 16 h for control). There was no observed change in BM monocyte pool. **Cytokine Release:** EHC stimulation increased the release of GM-CSF, IL-6, IL-1β, TNF-α, IL-8 and MCP-1. No effect on m-CSF and MIP-1β. CC particles induced increases in IL-6 and TNF-α; other cytokine levels did not differ from control. **Supernatant Instillation:** AM+EHC increased circulating WBC and band cell counts. Circulating monocyte counts were unaffected. AM+EHC showed a major increase in fraction and amount of monocyte released as well as faster clearance when compared to control. The BM monocyte pool was similar in all groups. **Monocyte Transit Time Through BM:** Exposure to EHC, CC only shortened the transit time of monocytes as compared to controls. AM+EHC also shortened monocyte transit time whereas AM+CC had a nonsignificant effect.
Reference: Gottipolu et al. (2009, 190360) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto, SH **Age:** 14-16 wk **Weight:** NR	DE (30-kW (40hp) 4-cylinder indirect injection Deutz diesel engine) (O_2- 20%, CO- 1.3-4.8 ppm, NO- <2.5-5.9 ppm, NO_2- <0.25-1.2ppm, SO_2 0.2-0.3 ppm, OC/EC- 0.3 ± 0.03) **Particle Size:** Number Median Diameter: Low- 83 ± 2 nm, High- 88. 2 nm; Volume Median Diameter: Low- 207 ± 2 nm, High- 225 ± 2 nm	**Route:** Inhalation **Dose/Concentration:** Low: 507 ± 4 µg/m^3; High: 2201 ± 14 µg/m^3 **Time to Analysis:** Exposed 4 h/days, 5 days/wk, 4 wk. Necropsied 1day post-exposure.	DE dose-dependently inhibited mitochondrial aconitase activity. DE caused 377 genes to be differentially expressed within WKY rats, most of which were downregulated, but none in SH rats. However, WKY rats had an expression pattern shift that mimicked baseline expression of SH rats without DE. These genes regulated compensatory response, matrix metabolism, mitochondrial function, and oxidative stress response.
Reference: Graff et al. (2005, 087956) **Species:** Rat **Cell Type:** Ventricular Myocytes	Zn; V **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 0, 6.25, 12.5, 25, or 50 µm **Time to Analysis:** Toxicity: 24 h post- exposure **Beat Rate:** 0.5, 1, 2, 4, and 24 h PE **PCR:** 6 and 24 h PE	**Beat Rate:** There were statistically significant reductions in spontaneous beat rate 4 and 24 h post-exposure (greater reductions were observed with Zn). **Inflammation:** Exposure to Zn or V (6.25-50 µm) for 6 h produced significant increases in IL-6, IL-α, heat shock protein 70, and connexin 43 (Cx43). **Impulse Conduction:** 24 h post-exposure, Zn induced significant changes in the gene expression of Kv4.2 and KvQLt, α-1 subunit of L-type Ca channel, Cx43, IL-6, and IL-1α. V produced a greater effect on Cx43 and affected only KvLQT1.
Reference: Gunnison and Chen (2005, 087956) **Species:** Mouse **Gender:** Male **Strain:** F2 generation DK ($ApoE^{-/-}$, $LDLr^{-/-}$) **Age:** 18-20 wk	CAPs (Tuxedo, NY) Copollutants measured: O_3 and NO_2. **Particle Size:** 389 ± 2 nm	**Route:** Whole-body Inhalation **Dose/Concentration:** CAPs: 131 ± 99 µg/m^3 (range 13-441 µg/m^3) O_3: 10 ppb NO_2: 4.4 ppb **Time to Analysis:** 6 h/days, 5 days/wk for approximately 4 mo. Tissue collection was performed 3-4 days after the last day of exposure.	**Gene Expression:** In CAPs-exposed heart tissue, the expression of Limd1 and Rex3 were the most consistently affected genes among the exposed mice. Limd1 was down regulated by 1.5-fold or greater from moderate baseline expression. Rex3 showed a relatively small increase in absolute expression.

Reference: Gurgueira et al. (2002, 036535) **Species:** Rat **Gender:** Male **Strain:** SD **Weight:** 250-300 g	CAPs; Carbon Black (CB from Fisher Scientific, Pittsburgh, PA): C (85.9 ± 0.2%); O (13 ± 0.2%); S (1.17 ± 0.02%) ROFA: obtained from an oil-fired power plant (Boston, MA) **Particle Size:** CAPs size range: 0.1-2.5 µm; CB and ROFA ($PM_{2.5}$)	**Route:** Whole-body Inhalation **Dose/Concentration:** CAPs: average mass concentration: 300 ± 60 µg/m^3; ROFA: 1.7 mg/m^3; CB: 170 µg/m^3 **Time to Analysis:** CAPs: 1, 3, and 5 h; ROFA: 30 min; CB: 5 h	**Oxidative Stress:** Rats breathing CAPs aerosols for 5 h showed significant oxidative stress, determined as in situ chemiluminescence (CL) in the lung, heart, but not in the liver. ROFA also triggered increases in oxidant levels but not particle-free air or CB. Increases in CL showed strong associations with the CAPs content of Fe, Al, Si and Ti in the heart. The oxidant stress imposed by 5 h exposure to CAPs was associated with slight, but significant increases in the lung and heart water content, with increased serum levels of lactate dehydrogenase, indicating mild damage to tissues. CAPs inhalation also led to tissue-specific increases in the activities of SOD and catalase.
Reference: Gursinsky et al. (1976, 015607) **Species:** Rat **Cell Type:** Fibroblasts isolated from adult male Wistar rats hearts	Fly ash (TAF98) **Particle Size:** NR	**Route:** In Vitro **Dose/Concentration:** TAF98: 0, 1, 2 3, 10, 25, 50, 100, 200 µg/mL **Time to Analysis:** 0, 5, 10, 30, 60, 120 min	Brief treatment of fibroblasts with fly ash triggered the immediate formation of ROS. Using phosphospecific antibodies the activation of p38 MAP kinase, p44/42 MAP kinase (ERK1/2) and p70S6 kinase. Prolonged incubation with fly ash increased the expression of collagen 1 and TGF-β1, but decreased mRNA levels of MMP9 and TNF-α. Cell proliferation was inhibited at high concentrations of fly ash. An increase in the level of advanced glycation end product modification of various cellular proteins was observed.
Reference: Hansen et al. (2007, 090703) **Species:** Mouse **Gender:** Female **Strain:** $ApoE^{-/-}$ and C57BL/6J $ApoE^{+/+}$ **Age:** 11-13 wk	DEP: SRM-2975 (NIST) **Particle Size:** DEP: 215 nm (geometric mean diameter)	**Route:** Intraperitoneal Injection **Dose/Concentration:** DEP: 0, 0.5 and 5 mg/kg; Aorta segments incubated with 0, 10 and 100 µg DEP/mL **Time to Analysis:** Sacrificed 1 h after ip injection.	Exposure to 0.5 mg/kg DEP caused a decrease in the endothelium-dependent Ach elicited vasorelaxation in $ApoE^{-/-}$ mice, whereas the response was enhanced in $ApoE^{+/+}$ mice. No significant changes were observed after administration of 5 mg/kg DEP. K^+ or phenylephrine induced constriction was not affected.
Reference: Hansen et al. (2007, 090703) **Species:** Mouse **Gender:** Female **Strain:** $ApoE^{-/-}$ and C57BL/6J $ApoE^{+/+}$ **Use:** Aorta rings used for in-vitro studies	DEP: SRM-2975 (NIST) **Particle Size:** DEP: 215 nm (geometric mean diameter)	**Route:** Cell Culture **Dose/Concentration:** 0, 10 and 100 µg DEP/mL **Time to Analysis:** Basal tone measured at 5 different points throughout experiment.	Exposure to 100 µg DEP/mL enhanced ACh-induced relaxation and attenuated phenylephrine-induced constriction. Vasodilatation induced by sodium nitroprusside was not affected by any DEP exposure.
Reference: Harder et al. (2005, 087371) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 12-15 wk	Carbon UFPs ((generated by Electric Spark Generator GFG 1000; Palas, Karlsruhe, Germany) **Particle Size:** 37.6 ± 0.7 nm (mean)	**Route:** Whole-body Inhalation **Dose/Concentration:** 180 µg/m^3 **Time to Analysis:** Days 1-3: baseline reading, Day 4: exposure to UFPs or filtered air for 4 or 24 h then sacrificed immediately following exposure period OR Sacrificed following 1-3 days recovery period.	**Cardiovascular Performance:** Mild but consistent increase in HR, which was associated with a significant decrease in HR variability during exposure (particle-induced alteration of cardiac autonomic balance, mediated by a pulmonary receptor activation). **Lung Inflammation and Acute-Phase Response:** BALF revealed significant but low-grade pulmonary inflammation. **Effects on Blood:** There was no evidence of an inflammation-mediated increase in blood coagulability; no changes in plasma fibrinogen or factor VIIa. **Pulmonary and Cardiac Histopathology:** Sporadic accumulation of particle-laden macrophages found in the alveolar region. No signs of cardiac inflammation or cardiomyopathy. **mRNA Expression Levels:** No significant changes in the lung or heart.

Reference: Hirano et al. (2003, 097345) **Species:** Rat **Cell Types:** Heart Microvessel Endothelial Cells (RHMVE)	Organic Extracts of DEP (DEP) and Organic Extracts of Ultra Fine Particles (UFP). (Urawa City, Saitama, Japan) **Particle Size:** DEP and UFP: <2.0 µm	**Route:** Cells Culture **Dose/Concentration:** NAC effects on viability: DEP: 25 µg/ml; UFP: 50 µg/ml mRNA levels for DEP and UFP: 0,1,3,10 µg/ml cell monolayer exposed to DEP and UFP: 1,10,100 µg/ml **Time to Analysis:** mRNA levels measured after 6 h incubation with DEP or UFP. Other parameters measured after 24 h.	**Cytotoxicity and Oxidative Stress:** LC50 values were 17 and 34 µg/mL for DEP and UFP respectively. The viability of DEP and UFP exposed cells was ameliorated by N-acetyl-L-cysteine (NAC). **mRNA Levels:** mRNA levels increased dose-dependently with DEP and HO-1 mRNA showed the most marked response to DEP. mRNA levels of antioxidant enzymes and heat shock protein 72 (HSP72) in DEP-exposed cells were higher than UFP exposed cells at the same concentration. The transcription levels of HO-1 and HSP72 in DEP and UFP-exposed cells were also reduced by NAC.
Reference: Hwang et al. (2005, 089454) **Species:** Mouse **Strain:** C57 and ApoE$^{-/-}$	CAPs (Tuxedo, NY) **Particle Size:** 389 ± 2 nm	**Route:** Whole-body Inhalation **Dose/Concentration:** CAPs Range: 5-627 µg/m^3. Mean CAPs Concentration: 133µg/m^3. Mean Concentrations of O_3 and NO_2 in CAPs: 10 and 4.4 ppb respectively. **Time to Analysis:** 6 h/day, 5 days/wk for 5 mo.	**Long-term Analysis:** Significant decreasing patterns of HR, body temperature, and physical activity in ApoE$^{-/-}$ mice. Nonsignificant changes for C57 mice. The chronic effect changes for ApoE$^{-/-}$ mice were maximal in the last three wk. **Short-term Analysis:** Dose-dependent relationship for HR variations in ApoE$^{-/-}$ mice. **Heart Rate Fluctuation:** HR fluctuations in ApoE$^{-/-}$ mice during the period of 3-6 h increased by 1.35 fold at the end of the exposure and during a 15 min period increases by 0.7 fold at the end of the exposure.
Reference: Inoue et al. (2006, 190142) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6- 7 wk	DEP (obtained from a 4Jb1-type light-duty, 4-cylinder, 2.74-L Isuzu diesel engine) Washed DEP (carbonaceous nuclei of DEP after extraction) and DEP-OC (organic chemicals in DEP extracted with CH_2Cl_2); Washed DEP+LPS and DEP-OC+LPS **Particle Size:** $PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** Washed DEP: 4 mg/kg. DEP-OC: 4 mg/kg. LPS: 2.5 mg/kg. Washed DEP+LPS and DEP-OC+LPS: respective additions of LPS to each component prior-experimentation. **Time to Analysis:** Sacrificed 24 h post single dose instillation.	Both DEP components exacerbated vascular permeability. The increased fibrinogen and E-selectin levels induced by LPS. This exacerbation was more prominent with washed DEP than with DEP-OC. Washed DEP+LPS significantly decreased protein C and antithrombin-III and elevated circulatory levels of IL-6, KC and LPs without significance.
Reference: Inoue et al. (2006, 097815) **Species:** Mouse **Gender:** Male **Strains:** C3H/HeJ (TLR-4 point mutant) and C3H/HeN (Control) **Age:** 6 wk	DEP (derived from 4 cyl, 2.74l light duty diesel engine) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 12 mg/kg **Time to Analysis:** 24 h	**Hematology:** DEP increased plasma fibrinogen in both strains but with a greater increase in the knockout mice than the wild type.
Reference: Ito et al. (2008, 096823) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto (Specific pathogen-free) **Age:** 13-14 wk	CAPs (f-PM), Yokohama City, Japan. **Particle Size:** 0.1-2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 0.6-1.5 mg/m^3 **Time to Analysis:** Three groups exposed to: (1) filtered air for 4 days, (2) filtered air for 3 days and CAPs for 1 day or (3) CAPs for 4 days. All groups exposed for a maximum of 4.5 h/days for 4 consecutive days.	**mRNA Expression and Cardiovascular Function:** In samples of heart tissue, the mRNA of cytochrome P450 (CYP) 1B1, heme oxygenase-1 (HO-1), and endothelin A (ETA) receptor were up-regulated by CAPs; their levels were significantly correlated with the cumulative weight of CAPs in the exposure chamber. The up-regulation of ETA receptor mRNA was significantly correlated with the increase in HO-1 mRNA and weakly with the increase in MBP.

A significant decrease of L/W with exposure to air pollution was detected in pulmonary and coronary arteries, whereas no effects of air pollution were observed in renal vessels.
Reference: Li et al. (2005, 088647) **Species:** Rat **Strain:** SD **Tissues/Cell Types:** Cultured HPAECs; Pulmonary Artery Rings (PARs)	Urban Particles (UPs SRM 1648) Major Constituents (mass fraction in %): Al (3.4), Fe (3.9), K (1.1). Minor Constituents (mass fraction in %): Na (0.43), Pb (0.66), Zn (0.48). Trace Constituents (ng/mg): As (115), Cd (75), Cr (403), Cu (609), Mn (786), Ni (82), Se (27), U (5.5), V (127). **Particle Size:** NR	**Route:** PARs: In vitro organ model HPAECs: grown to 80% confluence **Dose/Concentration:** PARs and HPAECs: 1 to 100 µg/mL; Losartan treatment: 0.2 µmol Captopril treatment: 100 µmol **Time to Analysis:** PARs were exposed to increasing doses of UPs from 1 to 100 µg/mL. Maximum tension was recorded within 5 min after each UPs dose. HPAECs: exposed to UPs from 1 to 100 µg/mL for up to 2 min	Effects of UPs on the constriction of isolated rat pulmonary PARs and the activation of extracellular signal-regulated kinases 1 and 2 (ERK1/2) and p38 mitogen-activated protein kinases (MAPKs) in HPAECs with or without Losartan at 1-100 µg/mL induced acute vasoconstriction. UPs also produced a time- and dose-dependent increase in phosphorylation of ERK1/2 and p38 MAPK. Losartan pre-treatment inhibited both vasoconstriction and activation of ERK1/2 and p38. The water soluble fraction of UPs was sufficient for inducing ERK1/2 and p38 phosphorylation, which was also inhibited by Losartan. Cu (CuSO4) and V (VOSO4), induced pulmonary vasoconstriction and phosphorylation of ERK1/2 and p38, but only phosphorylation of p38 was inhibited by Losartan. UPs induced activation of ERK1/2 and p38 was attenuated by Captopril.

Reference: Li et al. (2006, 156693) **Species:** Rat, Rabbit, and Human **Tissues/Cell Types:** Pulmonary Artery Rings (PARs) (rat); isolated buffer-infused lungs (rabbits) and cultured HPAECs **Strain:** SD Rats, New Zealand White Rabbits **Weight:** Rat: 200-350 g; Rabbit: 2.5-3.0 kg	Urban Particles (UPs SRM 1648). Major Constituents (mass fraction in %): Al (3.4), Fe (3.9), K (1.1). Minor Constituents (mass fraction in %): Na (0.43), Pb (0.66), Zn (0.48). Trace Constituents (ng/mg): As (115), Cd (76), Cr (403), Cu (609), Mg (786), Ni (82), Se (27), U (5.5), V (127). **Particle Size:** NR	**Route:** In Vitro **Dose/Concentration:** PARs and HPAECs: 1 to 100 µg/mL **Time to Analysis:** PARs: treatment given 15 min prior to exposure. Exposed to increasing doses of UPs from 1 to 100 µg/mL. Maximum tension was recorded within 5 min after each UPs dose. HPAECs: exposed to UPs from 1 to 100 µg/mL for 20 and 120 min.	**Effects of UP on H_20_2 Release:** Within minutes after UPs treatment, HPAEC increased H_2O_2 production that could be inhibited by DPI, APO, and NaN_3. The water soluble fraction of UPs as well as its two transition metal components Cu and V, also stimulated H_2O_2 production. NaN_3 inhibited H_2O_2 production stimulated by Cu and V, whereas DPI and APO inhibited only Cu-stimulated H_2O_2 production. Inhibitors of other H_2O_2-producing enzymes, including N-methyl-L-arginine, indomethacin, allopurinol, cimetidine, rotenone, and antimycin, had no effects. **Effects of UP-induced H_20_2 on MAPK Activation:** DPI but not NaN_3 attenuated UPs-induced pulmonary vasoconstriction and phosphorylation of ERK1/2 and p38 MAPKs. Knockdown of p47phox gene expression by small interfering RNA attenuated UPs-induced H_2O_2 production and phosphorylation of ERK1/2 and p38 MAPKs.
Reference: Lippmann et al. (2005, 087453) **Species:** Mouse **Strain:** C57 and ApoE$^{-/-}$	(March-September 2003). Chemical Composition: regional secondary sulfate (SS) characterized by high S, Si, and organic C; resuspended soil (RS) characterized by high concentrations of Ca, Fe, Al, and Si; RO-fired powered emissions of the Eastern U.S. identified by the presence of V, Ni, and Se; and motor vehicle (MV) traffic and other sources. Contributors to Average Mass: SS (56.1%), RS (11.7%), RO combustion (1.4%), MV traffic and other sources (30.9%) **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** $PM_{2.5}$ concentrated ten-fold, producing an average of 113 µg/m^3 **Time to Analysis:** 6 h/days, 5 days/wk for 5 mo. Parameters measured daily: during exposure, the afternoon after exposure, and late at night	**Associations Between Sources and Short-term Heart Rate Changes**: There were no significant associations between SS, RS, RO, and MV factors and HR in C57 mice at any of the three intervals. There were significant associations between $PM_{2.5}$ and the RS source factor and decreases in HR for the ApoE$^{-/-}$ mice during the daily CAPs exposures but no associations with the other factors. There was no residual association of HR with $PM_{2.5}$ or the RS factor later in the afternoon or late at night. In the afternoon, there was a significant association between decreases in HR and the SS factor for the ApoE$^{-/-}$ mice that had not been present during exposure and did not persist into the night time period. MV traffic and others were not significantly associated with HR during any of these three time periods. For the C57 mice, there were no significant associations of HR with $PM_{2.5}$ or any of its components during any of the three daily time periods. **Associations Between Sources and Short-term HRV Changes:** Signal noise during exposures did not permit reliable analyses of HRV changes during the hours of CAP exposure.
Reference: Lippmann et al. (2005, 087453) **Species:** Mouse **Gender:** NR **Strain:** ApoE$^{-/-}$, ApoE$^{-/-}$ LDLr$^{-/-}$, C57BL/6 **Age:** NR **Weight:** NR	CAPs (Sterling Forest, spring-summer 2003) **Particle Size:** $PM_{2.5}$	**Route:** Inhalation **Dose/Concentration:** $PM_{2.5}$ average concentration: 110 µg/m^3, Long-term average: 19.7 µg/m^3 **Time to Analysis:** Exposed 6 h/days, 5 days/wk, 5 or 6 mo. Semicontinuous EKG recordings.	HR increased in ApoE$^{-/-}$ mice but not C57 mice. HRF increased over the duration of the experiment. Atherosclerotic plaque deposits and coronary artery disease lesions occurred in both CAPs-exposed mice and controls, but invasive lesions were only present in CAPs-exposed mice. A gene affecting circadian rhythm was upregulated in double knockout mice. CAPs activated NF-κB. No inflammation occurred in the pulmonary system.
Reference: Lippman M et al. (2006, 091165) **Species:** Mouse **Gender:** Male **Strain:** ApoE$^{-/-}$ **Age:** 6 wk	CAPs from Tuxedo, NY. Component of interest: Ni. **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** Average daily CAPs: 85.6 µg/^{m3}; Average daily Ni: 43 ng/m^3 **Time to Analysis:** 6 h/day, 5 days/wk, for 6 mo (July 2004-January 2005). 10-s ECG, HR, activity, and body temperature data were sampled every 5 min for the duration of the experiment.	For the CAPs-exposed mice, on 14 days there were Ni peaks at approximately 175 ng/m^3 and usually low CAPs and V. For those days back-trajectory analysis identified a remote Ni point source. ECG measurements on CAPs-exposed and sham-exposed mice showed Ni to be significantly associated with acute changes in HR and HRV.

Study	Pollutant	Exposure	Effects
Reference: Lund et al. (2007, 125741) **Species:** Mouse **Gender:** Male **Strain:** ApoE$^{-/-}$ **Age:** 10 wk **Use:** Mice were placed on a high fat at the beginning of the exposure.	Varying dilutions of gasoline emissions: (generated using two 1996 model 4.3L General Motors V-6 engines, fueled with conventional, unleaded, non-oxygenated gasoline, equipped with stock exhaust systems). Composition for Hi, Med, and Lo dilutions: PM, NO_X, CO, and Total Hydrocarbons (THC) **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** FA: PM (2 µg/m^3), NO_X (0 ppm), CO (0.1 ppm), HC (0.1 ppm); Low (1: 90 dilution of exhaust): PM (8 µg/m^3), NO_X (2 ppm), CO (9 ppm), HC (0.9 ppm); Mid (1: 20): PM (39 µg/m^3), NO_X (12 ppm), CO (50 ppm), HC (8.4 ppm); High (1: 12): PM (61 µg/m^3), NO_X (19 ppm), CO (80 ppm), HC (12 ppm); High-filtered (1:12): PM (2 µg/m^3), NO_X (18 ppm), CO (80 ppm), HC (12.7 ppm). **Time to Analysis:** 6 h/day, 7 days/wk for 7 wk. Mice were sacrificed within 16 h PE. During the study period all animals concurrently exposed to the following: FA: 8 µg/m^3 and 40 µg/m^3; PM Whole Exhaust: 60 µg/m^3; or Filtered Exhaust w/ gases matching the 60 µg/m^3 concentration.	Inhalation exposure to gasoline engine emissions resulted in increased aortic mRNA expression of matrix metalloproteinase-3 (MMP-3), MMP-7, and MMP-9, tissue inhibitor of MMP-2, ET-1 and HO-1 in ApoE$^{-/-}$ mice; increased aortic MMP-9 protein levels were confirmed through immunochemistry. Elevated ROS were also observed in arteries from exposed animals, despite absence of plasma markers. Similar findings were also observed in the aortas ApoE$^{-/-}$ mice exposed to particle filtered atmosphere, implicating the gaseous components of the whole exhaust in mediating the expression of markers associated with vasculopathy.
Reference: Lund et al. (2007, 125741) **Species:** Mouse **Gender:** Male **Strain:** ApoE$^{-/-}$ **Age:** 10 wk **Weight:** NR	GEE (conventional unleaded, nonoxygenated, nonreformulated gasoline- ChevronPhillips Specialty Fuels Division) **Particle Size:** 0.150 µm (MMAD)	**Route:** Inhalation **Dose/Concentration:** PM: 60 µg/m^3, NO_2: 2 ppm, NO: 16 ppm, CO: 80 ppm, THC: 12.7 ppm **Time to Analysis:** Mice fed high-fat diet 30 days before exposure. Exposed 6 h/day, 1 or 7 days. Some groups dosed with Tempol or BQ-123. Killed within 18 h of last exposure.	Aorta gelatinase activity increased with GEE exposure time. MMP-2/9 activity spread throughout the vasculature by day 7. 7 day GEE exposure significantly increased the aorta protein expression of MMP-9, MMP-2, TIMP-2, and plasma MMP-9. Generally, in GEE-exposed mice, Tempol decreased TBARS and vascular ET-1, and BQ-123 decreased vascular ROS, ET-1, MMP-9, and gelatinase activity.
Reference: McQueen et al. (2007, 096266) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Weight:** 228-500 g	DEP: SRM 2975 (NIST) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 0.5 mL/rat of 1 mg/mL; 1-2.2 mg/kg **Time to Analysis:** 6 h. Pre-exposure: Vagotomy (sectioning of vagus nerve) or atropine, 1mg/kg i.p. administered 30 min prior, 2 and 4 h post.	**Cardiovascular Response:** Blood pressure and heart rate were unaffected. Average arterial O_2 increased after DEP, but not when compared for each animal. CO_2 and pH were not affected
Reference: Medeiros et al. (2004, 096012) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 60 days **Weight:** 20-30 g	CP: Carbon particles PSA: ROFA (solid waste incinerator hospital Sao Paulo, Brazil) PSB: electric precipitator, steel plant, Brazil) PSA/PSB Characteristics: Generally, PSB had greater component concentrations than PSA: Br (100+x), Cr (3x), Fe (10+x), Mn (2x), Rb (60+x), Se (7x), Zn (4x). PMA>PMB: Ce (3x), Co (10+x), La (100x), Sb (15x), V (50x). **Particle Size:** CP: 1.7 ± 2.5 µm (78%<2.5 µm) PMA: 1.2 ± 2.2 µm(98 %<2.5 µm) PMB: 1.2 ± 2.2 µm (98%<2.5 µm)	**Reference:** Intranasal Instillation **Dose/Concentration:** CP: 10 µg/mouse; 0.5mg/kg PSA: 0.1, 1 or 10 µg/mouse; 0.005, 0.05, 0.5 mg/kg PSB: 0.1, 1 or 10 µg/mouse; 0.005, 0.05, 0.5 mg/kg **Time to Analysis:** Single, 24 h	**Hematology:** PSA and PSB decreased leukocyte count (all 3 doses) and platelet count (2 high doses). No effect on hemoglobin, erythrocytes and reticulocytes was observed. Fibrinogen levels increased for both PSB and PSA with PSB seeing a higher increase. None of the effects were dose-dependent. **Bone Marrow:** Erythroblasts increased for PSA at all dose levels and PSB at mid and high dose levels (high variability).

Reference: Montiel-Davalos et al.(2007, 156778) **Species:** Human **Cell Types:** HUVEC (from primary human endothelial cells) and U937 (human leukemia pro-monocytic) cell cultures.	$PM_{2.5}$ and PM_{10} from Mexico City **Particle Size:** $PM_{2.5}$, PM_{10}	**Route:** In Vitro **Dose/Concentration:** HUVEC TNF-α (10 ng/mL), and a PM range of 5, 10, 20, and 40 μg/cm^2 concentrations. **Time to Analysis:** 6 or 24 h (early and late adhesion molecules respectively)	Results showed that both $PM_{2.5}$ and PM_{10} induced the adhesion of U937 cells to HUVEC, and their maximal effect was observed at 20 μg/cm^2. This adhesion was associated with an increase in the expression of all adhesion molecules evaluated for PM_{10}, and E-selectin, P-selectin, and ICAM-1 for $PM_{2.5}$. In general the maximum expression of adhesion molecules induced by $PM_{2.5}$ and PM_{10} was obtained with 20 μg/cm^2; however PM_{10}-induced expression was observed from 5 μg/cm^2. E-selectin and ICAM-1 had the strongest expression in response to particles.
Reference: Moyer et al. (2002, 052222) **Species:** Mouse **Gender:** Male and Female **Strain:** B6C3F1	In phosphide (InP), Co sulfate heptahydrate ($CoSO_4 \cdot 7H_2O$), Vanadium pentoxide(V_2O_5) Gallium arsenide (GaAs), Ni oxide (NiO), Ni subsulfide (Ni_3S_2), Ni sulfate hexahydrate ($NiSO_4 \cdot 6H_2O$), talc, and Mo trioxide (MoO_3) **Particle Size:** MMAD particle size (μm): InP (1.1-1.3), $CoSO_4 \cdot 7H_2O$ (1.5-1.8), V_2O_5: (1.0), GaAs: (1.0)	**Route:** Inhalation **Dose/Concentration:** High-Dose Concentration in Chronic Studies, Male (μg/m^3): InP: 0.3, $CoSO_4 \cdot 7H_2O$: 3.0, V_2O_5: 4.0, GaAs: 1.0 High-Dose Concentration in Sub-Chronic Studies, Male or Female (μg/m^3): InP: 100, $CoSO_4 \cdot 7H_2O$: 30, V_2O_5: 16, GaAs: 75 **Time to Analysis:** Phase One: Evaluation of heart, kidney and lung tissues from all control and high dose male B6C3F1 mice exposed by inhalation to 9 particulate compounds for a 2yr period. Phase Two: evaluated heart, lung, kidney and mesentery tissues of control and high dose male and female B6C3F1 mice from the 90-day studies of the 4-compounds demonstrating arteritis after a 2-yr period.	**Phase One:** High-dose males developed significantly increased incidences of arteritis over controls in 2 of the 9 studies (InP and $CoSO_4 \cdot 7H_2O$), while marginal increases of arteritis were detected in 2 additional studies (V_2O_5 and GaAs). In contrast, arteritis of the muscular arteries of the lung was not observed. Morphological features of arteritis in these studies included an influx of mixed inflammatory cells including neutrophils, lymphocytes, and macrophages. Partial and complete effacement of the normal vascular wall architecture, often with the extension of the inflammatory process into the periarterial connective tissue, was observed. **Phase Two:** Results showed that arteritis did not develop in the 90-day studies, suggesting that long-term chronic exposure to lower-dose metallic PM may be necessary to induce or exacerbate arteritis.
Reference: Mutlu et al. (2007, 121441) **Species:** Mouse **Gender:** Male **Strain:** 57BL/6 (IL-6$^{+/+}$ and IL-6$^{-/-}$) **Age:** 6-8 wk **Weight:** 20-25 g	PM_{10} from ambient air in Düsseldorf, Germany **Particle Size:** PM_{10}	**Route:** IT Instillation **Dose/Concentration:** PM_{10}: 10 μg; Clodronate: 120 mg **Time to Analysis:** For alveolar macrophage depletion, clodronate instilled into mice lungs following endotracheal intubation 48 h prior to instillation of PM. Parameters measured 24 h post-exposure.	Mice treated with PM_{10} exhibited a shortened bleeding time, decreased prothrombin and partial thromboplastin times (decreased plasma clothing times), increased levels of fibrinogen, and increased activity of factors II, VIII, and X. This prothrombotic tendency was associated with increased generation of intravascular thrombin, an acceleration of arterial thrombosis, and an increase in BALF concentration of prothrombotic IL-6. IL-6$^{-/-}$ mice were protected against PM-induced intravascular thrombin formation and the acceleration of arterial thrombosis. Depletion of macrophages by the IT administration of liposomal clodronate attenuated PM-induced IL-6 production and the resultant prothrombotic tendency.
Reference: Nadziejko et al. (2002, 087460) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 16 wk	CAPs ($PM_{2.5}$) from Tuxedo, NY. (SO_2, NO_2 O_3 and NH_3 were removed prior to exposure). H_2SO_4 (fine and ultrafine) **Particle Size:** Ultrafine H_2SO_4 50-75 nm (MMAD)	**Route:** Nose-only Inhalation **Dose/Concentration:** CAPs: 80 and 66 μg/m^3 (avg 73); Fine H_2SO_4: 299, 280, 119, and 203 μg/m^3 (avg 225); Ultrafine H_2SO_4: 140, 565, 416, 750 μg/m^3 (avg 468) **Time to Analysis:** 4 h/exposure	Exposure to CAPs caused a striking decrease in respiratory rate that was apparent soon after the start of exposure and stopped when exposure to CAPs ceased. The decrease in respiratory rate was accompanied by a decrease in HR. Exposure of the same animals to fine-particle-size H_2SO_4 aerosol also caused a significant decrease in respiratory rate similar to the effect of CAPs. Ultrafine H_2SO_4 had the opposite effect on respiratory rate compared to CAPs.
Reference: Nadziejko et al. (2004, 055632) **Species:** Rat **Gender:** Male **Strain:** F344 **Age:** 18 mo	PM/CAPs (Tuxedo, NY) UFC (lab generated) SO_2 **Particle Size:** PM (Size Range): 0.5-2.5μm; UFC (MMAD): 30-50 nm	**Route:** Nose-only Inhalation **Dose/Concentration:** PM (μg/m^3): 161-200, avg. 180; UFC (μg/m^3): 500-1280, avg. 890; SO_2 (ppm): 1.2, 1.2, avg. 1.2 **Time to Analysis:** A total of 8 exposures were performed: 2 exposures to CAPs, 2 exposures to UFC, 4 exposures to SO_2. All three pollutants were tested w/ a crossover design so that each group alternated exposure to air and to pollutant. Exposures lasted 4 h and were performed at least 1wk apart. Parameters measured throughout duration of experiment.	Old F344 rats had many spontaneous arrhythmias. There was a significant increase in the frequency of irregular and delayed beats after exposure to CAPs. The same rats were subsequently exposed to UFC, SO_2 or air with repeated crossover design. In these experiments there was no significant change in the frequency of any category of spontaneous arrhythmia following exposure to UFC or SO_2.

Study	Pollutant	Exposure	Effects
Reference: Nemmar et al. (2008, 096566) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Weight:** 440 ± 14 g	DEP (SRM 2975) **Particle Size:** <1 µm	**Route:** Intravenous via the tail vein **Dose/Concentration:** DEP: 0.02mg or 0.1mg DEP/kg (corresponding to about 8 µg or 44 µg DEP/rat) **Time to Analysis:** 48 h following systemic administration of saline or DEP	Intravenous administration of DEP (0.1 mg/kg) triggered systemic inflammation characterized by an increase in monocyte an granulocyte numbers. Both doses of DEP caused a reduction of RBC numbers and hemoglobin concentration. TEM analysis of RBCs after in vitro incubation (5 µg/mL) or in vivo administration of DEP, revealed the presence of ultrafine-sized aggregates of DEP within the RBC. Larger aggregates were also taken up by the RBC. The myocardial morphology and capillary bed were not affected by DEP exposure.
Reference: Nemmar et al. (2007, 156800) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 16 wk **Weight:** 424 ± 8 g	DEP (SRM 2975) **Particle Size:** NR	**Route:** Tail Vein Injection **Dose/Concentration:** 8, 42, or 212 µg DEP/rat (150µl of 0.02, 0.1, or 0.5 mg/kg) **Time to Analysis:** 24 h	**Effect of DEP on Blood Pressure:** Significant decrease on BP in DEP-exposed rats at doses of 0.02 mg/kg, compared with mean BP observed in controls. **Effect of DEP on HR**: Doses of 0.02, 0.1, and 0.5 mg/kg in rats, resulted in significant reduction of HR compared to controls. **Effect of DEP on Tail Bleeding Time:** Shortening of tail bleeding time in rats exposed to 0.02, 0.1, and 0.5 mg/kg. The shortening was significant at the dose of 0.02 and 0.5 mg/kg compared w/ controls. Platelet counts in blood did not significantly increased post-DEP administration. **Effect of DEP on WBC and RBC Numbers:** No significant effect of DEP at doses of 0.02, 0.1 and 0.5 mg/kg on the numbers of granulocytes, monocytes, or lymphocytes compared with control.
Reference: Nemmar et al. (2003, 096567) **Species:** Hamster **Gender:** Male and Female **Weight:** 100-110 g	DEP (SRM 1650) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 120 µl (5, 50, or 500 µg/animal) **Time to Analysis:** In-vivo: formation and embolization of thrombus were continuously monitored for 40 min. Ex-vivo: animals were ITly instilled w/ DEPs (0 or 50 µg per animal), and blood was collected 5, 15, 30, and 60 min post-instillation. In-vitro: Saline or saline-containing DEPs (0.1, 0.5, 1, and 5 µg/mL) was added to venous blood from untreated hamsters, and closure time was measured in the PFA-100 after 5 min/animal.	Doses of 5-500 µg enhanced experimental arterial and venous platelet-rich thrombus formation in-vivo. Blood samples taken from hamsters 30 and 60 min after instillation of 50 µg of DEPs yielded accelerated aperture closure (platelet activation) ex-vivo, when analyzed in the PFA-100. The direct addition of as little as 0.5 µg/mL DEPs to untreated hamster blood significantly shortened closure time in vitro.
Reference: Nemmar et al. (2004, 087959) **Species:** Hamster **Gender:** Male and Female **Weight:** 100-110 g	DEP (SRM 1650); Positively Charged Polystyrene Particles (PCPSP) **Particle Size:** PCPSP: 400 nm; DEP: NR	**Route:** IT Instillation **Dose/Concentration:** DEP: 50 µg/animal, or PCPSP: 500 µg/animal **Time to Analysis:** Pretreatment Phase: Hamsters were pretreated w/ Dexametasone IP (5 mg/kg) or IT (0.1 or 0.5 mg/kg) or Sodium Cromoglycate given IP (40 mg/kg), 1 h before DEP or vehicle instillation. Thrombosis: In-vivo thrombogenesis assessed 24 h post-instillation of DEP or vehicle.	DEP increased thrombosis without elevating plasma vWF. The IT instillation of PCPSP equally produced histamine release and enhanced thrombosis. Histamine in plasma resulted from basophil activation. IP pretreatment with Dexametasone abolished the DEP-induced histamine increase in BALF and plasma and abrogated airway inflammation and thrombogenicity. The IT pretreatment with Dexametasone showed a partial but parallel inhibition of all these parameters. Pretreatment with Sodium Cromoglycate strongly inhibited thrombogenicity, and histamine release.
Reference: Nemmar et al. (2003, 097487) **Species:** Hamster **Gender:** Male and Female **Weight:** 100-110 g	Ultrafine Particles: Unmodified Polystyrene Particles (UPSPs); Negatively Charged Carboxylate-Modified Polystyrene Particles (NCC-MPSPs); Positively-Charged Amine Modified Polystyrene Particles (PCA-MPSPs) **Particle Size:** UPSPs: 60 nm; NCC-MPSPs: 60 nm; PCA-MPSPs: 60 or 400 nm	**Route:** IT Instillation **Dose/Concentration:** 5, 50, and 500 µg/animal in 120 µl saline **Time to Analysis:** 1 h post-instillation	Unmodified and negative UFPs did not modify thrombosis. Positive UFPs increased thrombosis at 500 and 50 µg/animal, but not at 5 µg/animal. Positive 400 nm particles (500 µg/animal) did not affect thrombosis. PFA-100 analysis showed that platelets were activated by the in-vitro addition of positive UFPs and 400 nm particles to blood.

Reference: Nemmar et al. (2003, 087931) **Species:** Hamster **Weight:** 100-110 g	DEP (SRM 1650) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 50 µg/animal in 120 µl saline **Time to Analysis:** 1, 3, 6, and 24 h	At 1, 6, and 24 h after instillation of 50 µg DEPs, the mean size of in-vivo induced and quantified venous thrombosis was increased by 480, 770, and 460%, respectively. Platelets activation in blood was confirmed by a shortened closure time in the PFA-100 analyzer. In plasma, histamine was increased only at 6 and 24 h. Pre-treatment with a H1 receptor antagonist (diphenhydramine, 30 mg/kg intraperitoneally) did not affect DEP-induced thrombosis or platelet activation at 1 h; however both were markedly reduced at 6 and 24 h.
Reference: Niwa et al. (2007, 091309) **Species:** Mouse **Gender:** Male **Strain:** LDLr/KO **Age,:** 6 wk (n = 20) **Use:** IT CB dispersion; 10-14 wk acute effect of CB dispersion on circulating CRP	Carbon Black **Particle Size:** 23-470 nm (mean size 120.7 nm)	**Route:** IT Dispersion **Dose/Concentration:** IT CB Dispersion Study: 1 mg per animal/wk; Acute Effect of CB Dispersion on Circulating CRP Study: 1mg/animal (single administration) **Time to Analysis:** IT CB Dispersion Study: 1x/wk for 10 wk Acute Effect of CB Dispersion on Circulating CRP Study: Single CB administration, blood samples collected 24 h post-administration	**IT CB Dispersion Study:** Although no difference in body weight (bw) between the four groups was observed at baseline, and all mice experienced an increase in bw with advancing age, the mice treated with CB tended to be smaller than those treated with vehicle (air). No significant differences were observed in cholesterol and TG levels among the for groups. Development of aortic lipid-rich lesions occurred in mice under a 0.51% cholesterol diet with or without CB infusion, but not in the mice fed a 0% cholesterol diet. **Acute Effect of CB Dispersion on Circulating CRP Study:** Circulating levels of CRP were significantly higher in mice exposed to CB versus those exposed to air, indicating an acute inflammatory response. Although the presence of CB in pulmonary macrophage-like cells in CB treated mice under 0.51% cholesterol diet was confirmed, CB was not detected in aortas, livers, kidneys, or spleens.
Reference: Niwa et al. (2007, 091309) **Species:** Mouse **Cell Types:** RAW264.7	Carbon Black (CB); Water-Soluble Fullerene ($C_{60}(OH)_{24}$); Fluoresbrite Carboxylate Microspheres; Ox-LDL; Acetylated-LDL **Particle Size:** Carbon Black and $C_{60}(OH)_{24}$: 7.1 nm (SD 2.4); Fluoresbrite Carboxylate Microspheres: 6 nm	**Route:** Cell Culture **Dose/Concentration:** CB: 1, 10, 100 µg/mL; $C_{60}(OH)_{24}$: 20, 100ng/mL **Time to Analysis:** RAW264.7+CB for 24 h, 13 days, and 50 days; RAW264.7+ $C_{60}(OH)_{24}$ for 24 h or 10 days; RAW264.7+ $C_{60}(OH)_{24}$ for 8 days, then co-treated w/ Ox-LDL for an additional 48 h; RAW264.7+Ox-LDL for 5 days, and then co-cultured w/ C60(OH)24 for an additional 48 h; RAW264.7+ 6 nm beads: 3 days, the Ox-LDL or acetylated-LDL added for 24 h	CB alone had no significant effects on RAW264.7 cell growth. $C_{60}(OH)_{24}$ alone or CB and $C_{60}(OH)_{24}$ together w/ Ox-LDL induced cytotoxic morphological changes, such as Ox-LDL uptake-induced foam cell-like formation and decreased cell growth, in a dose-dependent manner. $C_{60}(OH)_{24}$ induced LOX-1 protein expression, pro-matrix metalloprotease-9 protein secretion, and tissue factor mRNA expression in lipid-laden macrophages. Although CB or $C_{60}(OH)_{24}$ alone did not induce platelet aggregation, $C_{60}(OH)_{24}$ facilitated ADP-induced platelet aggregation. $C_{60}(OH)_{24}$ also acted as a competitive inhibitor of ADP receptor antagonists in ADP-mediated platelet aggregation.
Reference: Niwa et al. (2008, 156812) **Species:** Rat **Strain:** SD **Age:** 6 wk	CB from Kyoto, Japan **Particle Size:** Mean size (nm) ± SD determined at 1, 8, 15, 22, and 29 day post-exposure was 118.1 ± 2.4, 119.1± 2.7, 122.2 ± 2.0, 122.4 ± 2.5 and 121.0 ± 3.6 respectively	**Route:** Whole-body Inhalation **Dose/Concentration:** 15.6 ± 3.5 mg/m^3 **Time to Analysis:** 6 h/day, 5 days/wk, for a total of 4 wk. BP and HR were measured by tail-cuff plethysmography at 1, 14, and 28 day post -exposure. Sacrificed At 1, 7, 14, 28, and 30 day post-exposure	Although the presence of CB was confirmed in pulmonary macrophages, electron microscopic survey did not detect CB in other tissues including, liver, spleen and aorta. CB exposure raised blood pressure levels in a exposure-time dependent manner. Levels of circulating inflammatory marker proteins, including monocyte chemo attractant protein-1, IL-6, and CRP, were higher in the CB treated groups than in control groups.
Reference: Nurkiewicz et al. (2004, 087968) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 7-8 wk	ROFA (from Everett, MA). Major metal contaminants are: Fe, Al, V, Ni, Ca, and Z. Main soluble metals are: Al, Ni, and Ca. **Particle Size:** 2.2 µm (ROFA mean count diameter)	**Route:** IT Instillation **Dose/Concentration:** ROFA group: 0.1, 0.25, 1, or 2 mg/rat. Vehicle control group: 300 µl saline. Particle control group: TiO_2 0.25 mg/rat. **Time to Analysis:** After single IT instillation of a particular dose, all rats recovered for 24 h.	**Saline Treated Rats:** A23187 dilated arterioles up to 72 ± 7% max. **ROFA and TiO_2 Exposed Rats:** A23187-induced dilation was significantly attenuated. **Sensitivity of Arteriolar Smooth Muscle to NO:** Similar in saline treated and ROFA exposed rats. **Other:** Significant increase in venular leukocyte-adhesion and rolling observed in ROFA exposed rats.

Study	Pollutant	Exposure	Effects
Reference: Nurkiewicz et al. (2006, 088611) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 7-8 wk	ROFA from Everett, MA **Particle Size:** ROFA mean count diameter: 2.2 µm; TiO_2 mean diameter: 1.0 µm	**Route:** IT Instillation **Dose/Concentration:** ROFA group: 0.1 or 0.25 mg/rat. Vehicle control group: 300 µl saline. Particle control group: TiO_2 0.1 or 0.25 mg/rat. **Time to Analysis:** After single IT instillation of a particular dose, all rats recovered for 24 h.	**ROFA or TiO_2 Exposure and Arteriolar Dilation:** Exposure caused a dose-dependent impairment of endothelium-dependent arteriolar dilation. **ROFA or TiO_2 Exposure and Arteriolar Constriction:** Exposure did not affect microvascular constriction in response to PHE. **ROFA and TiO_2 and Leukocyte Rolling and Adhesion:** Exposure significantly increased leukocyte rolling and adhesion in aired venules, and these cells were identified as PMN leukocytes. **ROFA and TiO_2 and MPO:** MPO was found in PMN leukocytes, adhering to the systemic microvascular wall. Evidence suggests that some of this MPO had been deposited in the microvascular wall. There was also evidence of oxidative stress in the microvascular wall.
Reference: Nurkiewicz et al. (2008, 156816) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 6-7wk **Weight:** NR	TiO_2 (DeGussa, Sigma-Aldrich) **Particle Size:** Fine- 1 µm, UF- 21 nm	**Route:** Whole-body Inhalation **Dose/Concentration:** Concentrations: Fine- 3-16 mg/m^3; UF- 1.5-12 mg/m^3; Dose: Fine- 8, 20, 36, 67, 90 µg; UF- 4, 6, 10, 19, 30 µg **Time to Analysis:** Acclimated 5 days. Exposed 4-12 h. Sacrificed 24 h post-exposure.	Particle accumulation within AMs, anuclear macrophages, particle-laden AMs intimately associated with the alveolar wall were all present in exposed rats. Calcium ionophore impaired arteriolar dilation in a dose-dependent manner in UF and fine exposed rats. UF produced greater systemic microvascular dysfunction. Microvascular dysfunction was the same for three groups of rats exposed to 30 µg UF TiO_2 under different conditions.
Reference: Nurkiewicz et al. (2009, 191961) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 7-8 wk **Weight:** NR	Fine TiO_2 (Sigma-Aldrich, St. Louis, MO) (~99% rutile) TiO_2 nanoparticles (DeGussa-Aeroxide TiO_2 P25, Parsippany, NJ) (80% anatase, 20% rutile) **Particle Size:** Fine TiO_2- MMAD: 402 nm, Primary size: <5 µm, ,CMD: 710 nm; Nano-TiO_2- MMAD: 138 nm, Primary size: 21 nm, , CMD: 100 nm	**Route:** Aerosol Inhalation **Dose/Concentration:** 1.5-16mg/m^3 **Time to Analysis:** Acclimated 5 days. Exposed 240-720 min. Anesthetized 24 h post-exposure. Intravital microscopy, NO measurement, microvascular oxidative stress measurement, nitrotyrosine staining.	**Arteriolar Dilation:** Nano-TiO_2 significantly impaired endothelium-dependent arteriolar dilation. Equivalent levels of arteriolar dysfunction were found in fine and nano-TiO_2. Arteriolar dilation in response to abluminal microiontophretic application of SNP was not different from the controls or between the exposure groups. Arteriolar dilation was partially restored by radical scavenging with TEMPOL and catalase, NADPH oxidase with apocynin, and MPO inhibition with ABAH. **Microcirculation:** ROS increased in both groups. Nano-TiO_2 significantly increased the area of tissue containing nitrotyrosine in the lung and spinotrapezius microcirculation. **NO:** Fine and nano-TiO_2 significantly and dose-dependently decreased stimulated NO production in isolated microvessels. NO production was increased by radical scavenging with TEMPOL and catalase or NADPH oxidase with apocynin, and was largest in the fine TiO_2 group.

Study	Pollutant	Exposure	Effects
Reference: Okayama et al. (2006, 156824) **Species:** Rat **Cell Type:** Ventricular Cardiac Myocytes from Wistar Rats, approximately 3 days old	DEP (Tsukuba, Japan) DEPE: 5g of DEP in 5 mL PBS containing 0.05% Tween 80. Others: Catalase, LDH, MPG and SOD. **Particle Size:** DEP mass median diameter: 0.34 µm.	**Route:** In Vitro **Dose/ Concentration:** DEPE: 0-100 µg/mL; MPG: 0-1 mM; SOD: 800 U/mL; Catalase: 500 U/mL **Time to Analysis:** cells were incubated for 1, 2, 4, or 8, 24 or 48 h. LDH Activity of Supernatant: 24 h post-DEPE exposure. SOD, Catalase, MPG on DEPE-induced Toxicity: SOD, catalase or MPG was added to cells w/ or w/o DEPE & incubated for 4 or 24 h. Medium then replaced w/serum-free & cells incubated for another 24 h to analysis.	**Cytotoxic Effects of DEPE on Cardiac Myocytes:** DEPE above 20 µg/mL damaged cardiac myocytes in a time and concentration-dependent manner in both long- and short-term exposure conditions. However damage was greater after long-term exposure. LDH activity showed a concentration-dependent increase at higher levels of exposure (greater than 20 µg/mL). **Effects of ROS Scavenging Enzymes and Antioxidant on DEPE-induced Cell Damage:** SOD or catalase attenuated 50 µg/mL DEPE-induced cell damage compared with DEPE-treated groups lacking antioxidant enzymes. Co-incubation with SOD and catalase showed more protective effects towards DEPE-induced cell damage, although these effects were not statistically significant from cells treated with SOD only. MPG attenuated 50 µg/mL DEPE-induced cell damage in a concentration-dependent manner in both long and short-term exposure conditions. Especially in long-term exposure MPG showed strong protective effects against DEPE-induced cell damage. Cell viability was not affected by SOD, catalase, or MPG.
Reference: Proctor et al. (2006, 088480) **Species:** Rat **Gender:** Male **Age:** 12 wk **Use:** Thoracic Aorta from cp/cp and +/? Male Rats cp/cp = homozygous for cp gene. Prone to obesity and insulin resistant. +/? = heterozygous for either +/cp or +/+. Lean and metabolically normal.	ROFA from Birmingham, AL **Particle Size:** 1.95 ± 0.18 µm (aerodynamic diameter)	**Route:** Protocol 1: Used two aorta rings per each experimental treatment group (4 groups total). Protocol 2: Used four rings. **Dose/Concentration:** Protocol 1: exposed to 12.5 µg/mL ROFA-L (at 10 mg/mL). Protocol 2: exposed to 1.56, 3.25, 6.26, 12.5 µg/mL ROFA-L (at 10 mg/mL). **Time to Analysis:** Protocol 1: Cells treated with 12.5 µg/mL ROFA-L and/or 104mol/L L-NAME for 20 min Protocol 2: Parameters measured after ROFA-L only treatment Contractile response to phenylephrine (PE) was measured	ROFA-L (12.5 µg/mL) increased PE-mediated contraction in obese, but not in lean rat aortae. Effect was exacerbated by L-NAME, and it reduced ACh-mediated relaxation in obese and lean aortae. Initial exposure of aortae to ROFA-L caused a small contractile response, which was markedly greater on second exposure in the obese aortae but marginal in lean.
Reference: Radomski et al. (2005, 091377) **Species:** Rat **Strain:** Wistar Kyoto	Carbon Nano Particles (CNPs) (purchased from SES Research, Houston, TX): Multiplewall Nanotubes (MWNT); Single wall Nanotubes (SWNT); C60 Fullerenes (C60CS); Mixed Carbon Nanoparticles (MCN) PM: (SRM1648) (NIST) **Particle Size:** CNPs: NR; PM: 1.4 µm average size	**Route:** Simultaneous single PM injection into femoral vein as $FeCl_3$ injected to induce carotid thrombosis **Dose/Concentration:** 0.5 mL suspension of 50 µg/mL of PM in 0.9% NaCl solution. **Time to Analysis:** Blood flow continuously monitored for 900 s.	**Vascular Thrombosis:** $FeCl_3$ induced carotid artery thrombosis and MCN had an amplifying effect in the development of thrombosis. Infusions of MCN, SWNT, and MWNT significantly accelerated the time and rate of development of carotid artery thrombosis in rats. SRM1648 was less effective than CNPs in inducing thrombosis, while C60CS exerted no significant effect on the development of vascular thrombosis.
Reference: Radomski et al. (2005, 091377) **Species:** Human **Cell Types:** Platelets **Use:** Human platelet aggregation	Carbon Nano Particles (CNPs) (purchased from SES Research, Houston, TX): Multiplewall Nanotubes (MWNT); Singlewall Nanotubes (SWNT); C60 Fullerenes (C60CS); Mixed Carbon Nanoparticles (MCN); PM (SRM1648) **Particle Size:** CNPs: NR; PM: 1.4 µm average size	**Route:** Cell Culture (2.5×10^8 platelets/mL) **Dose/Concentration:** CNPs: 0.2-300 µg/mL; PM: 5-300 µg/mL **Time to Analysis:** Prostacyclin (PGI2), S-nitroso-glutathione (GSNO), aspirin, 2-methylthio-AMP, phenanthroline, EDTA and Go6976 were pre-incubated w/ platelets for 1 min before particle addition. Particles added to platelets and platelet aggregation studied for 8min.	**Platelet Aggregation:** All CNPs, except C60CS, stimulated platelet aggregation (MCN ≥ SWNT>MWNT>SRM1648). All particles resulted in upregulation of GPIIb/IIIa in platelets. In contrast, particles differentially affected the release of platelet granules, as well as the activity of thromboxane-, ADP, matrix metalloproteinase- and protein kinase C-dependent pathways of aggregation. Particle-induced aggregation was inhibited by prostacyclin and GSNO, but not by aspirin.

Clackamas, OR) Measured Components: EC, OM, NO_3, SO_4, NH_4, metals **Particle Size:** ~0.25 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** Low: 30 µg/m^3 Mid-low: 100 µg/m^3 Mid-high: 300 µg/m^3 High: 1000 µg/m^3 **Time to Analysis:** 6 h/day, 7days /wk for 1 wk or 6 mo. Immediate post-exposure analysis.	**Organ Weights:** Liver declined in rats of both genders at 1 wk and female rats at 6 mo. Lung volume increased and lung weight decreased in female rats at 6 mo. Spleen weight increased in female mice and rats at 1wk. Thymus weight decreased in male rats at 1wk. **Clinical Chemistry:** Cholesterol decreased at the high dose for male rats at 1wk and 6 mo and increased at mid-low and mid-high doses for female rats at 6 mo. ALP decreased for rats of both genders at 1wk and 6 mo for mid-low, mid-high and high dose levels (14-38%). AST decreased by 24% in male rats at 1wk with high dose. No effect on females. Creatinine serum levels decreased in males at 1wk at mid-high and high dose by 13%. No effect observed at 6 mo. BUN/Cre ratio decreased in females at 1wk (25%) and both genders at 6 mo at mid-high and high dose (18-19%). **Hematology:** Hemoglobin and hematocrit increased in 6 mo male rats. Bilirubin increased in female rats at 6 mo at high dose. Platelets increased for male and female rats at 1wk (21%, 19% respectively). No effect observed at 6m. WBC increased in males at 1wk.
Reference: Reed et al. (2004, 055625) **Species:** Rat, Mouse **Gender:** Male and Female **Strain:** CDF (F344)/CrlBR (rat), A/J (mouse) **Age:** 12 wk	DE: generated from two 2000 model 5.9 L Cummins ISM turbo diesel engines Co-exposure to 8 gas and 8 solid exhaust components measured **Particle Size:** 0.10 - 0.15 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** Low: 30 µg/m^3 Mid-low: 100 µg/m^3 Mid-high: 300 µg/m^3 High: 1000 µg/m^3 **Time to Analysis:** 6 h/day, 7 days/wk for 1wk or 6 mo. Analyzed 1 day post-exposure.	**Organ Weights:** Kidney weight increased after 6m for both males and female rats at the high dose. Kidney and liver weight increased for female mice at all dose levels at 6 mo. Lung weight increased at high dose at 6mo for female mice and male rats. Spleen weight decreased in male mice at the low and mid-high levels. **Clinical Chemistry:** There was a massive decrease in cholesterol (24%) for rats of both genders after 1 wk and a smaller decrease for male rats at 6 mo. GGT significantly increased at 6 mo for male and female rats at the mid-high and high dose. ALP increased in male rats at 1 wk by 10%. AST decreased at mid-high (15%) and high dose in female rats at 6 mo. BUN and BUN/Creatine declined (19%, 17%) in female rats at mid-high and high doses after 6 mo. BUN increased by 21% at mid-low, mid-high and high doses in male rats at 1wk. **Hematology:** WBC decreased in high females after 6 mo. Factor VII (blood clotting) decreased in MH and HR males after 1wk and male and female HR after 6 mo. Thrombin-antithrombin complex declined massively but only in males after 1wk.
Reference: Reed et al. (2008, 156903) **Species:** Rat **Gender:** Male, Female **Strain:** CDF (F344)/CrlBR, SH **Age:** NR **Weight:** NR	GEE (two 1996 General Motors 4.3-L V-6 engines; regular, unleaded, non-oxygenated, non-reformulated Chevron-Phillips gasoline, U.S. average consumption for summer 2001 and winter 2001-2002) **Particle Size:** 150 nm (MMAD)	**Route:** Whole-body Inhalation **Dose/Concentration:** PM: Low- 6.6 ± 3.7 µg/m^3, Medium- 30.3 ± 11.8 µg/m^3, High- 59.1 ± 28.3 µg/m^3 **Time to Analysis:** 2 wk quarantine period in chamber. Exposed 6 h/day, 7 days/wk, 3 day-6 mo. SH- surgery to implant telemeter in peritoneal cavity. 4 wk recovery. ECG data obtained every 15 min beginning 3 day pre-exposure, 7 day exposure, 4 day post-exposure.	**Organ Weight:** At 6 mo exposure, the heart weights of male and female rats increased and male rats' seminal vesicle weight decreased. **Clinical Chemistry:** Serum alanine aminotransferase, aspartate aminotransferase, and phosphorus decreased in medium and high-exposure females. **Hematology:** Hematocrit, red blood cell count, and hemoglobin dose-dependently increased for both genders at both time points. Plasma fibrinogen increased at 1wk in males. **CV Effects in SH Rat:** Lipid peroxides were significantly increased in males in the high exposure group. TAT complexes decreased in females in the high exposure group. **Removal of Emission PM:** The removal of emission PM strongly linked PM to increased seminal vesicle weight, red blood cell counts, LDH, lipid peroxides, and methylation.

Study	Pollutant	Exposure	Effects
Reference: Rhoden et al. (2005, 087878) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** Adult **Weight:** 300 g	Urban Ambient Particles (UAPs): SRM-1649; CAPs (Boston, MA) **Particle Size:** NR	**Route:** UAPs: IT Instillation. CAPs: Inhalation **Dose/Concentration:** UAPs: 750 µg suspended in 300 µl saline; CAPs: 700 ± 180 µg/m^3 **Time to Analysis:** UAPs: 30 min post-instillation. CAPs: immediately after 5 h exposure period	**Oxidative Stress and HR Function:** UAPs instillation led to significant increases in heart oxidants. HR increased immediately after exposure and returned to basal levels over the next 30 min. SDNN was unchanged immediately after exposure, but significantly increased during the recovery phase. **Role of ROS in Cardiac Response:** Rats were treated with 50 mg/kg NAC 1 h prior to UAPs instillation or CAPs inhalation. NAC prevented changes in heart rate and SDNN in UAPs-exposed rats. **Role of the Autonomic Nervous System in PM-induced Oxidative Stress**: Rats were given 5 mg/kg atenolol, 0.30 mg/kg glycopyrrolate, or saline immediately before CAPs exposure. Both atenolol and glycopyrrolate effectively prevented CAPS-induced cardiac oxidative stress.
Reference: Rivero et al. (2005, 088653) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 3 mo **Weight:** ~250 g	$PM_{2.5}$, collected from heavy traffic area in Sao Paulo, Brazil. $PM_{2.5}$ Composition (%): S (3.05), As (0.30), Br (0.21), Cl (2.09), Co (2.65), Fe (2.67), La (5.42), Mn (0.64), Sb (0.21), Sc (3.25), Th (8.14) **Particle Size:** $PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** 100 or 500 µg of $PM_{2.5}$. **Time to Analysis:** 24 h post-instillation	**Hematology:** Total reticulocytes significantly increased at both $PM_{2.5}$ doses, while hematocrit levels increased in the 500 µg group. Quantification of segmented neutrophils and fibrinogen levels showed a significant decrease, while lymphocytes counting increased with 100 µg of $PM_{2.5}$. **Pulmonary Vasculature:** Significant dose-dependent decrease of intra-acinar pulmonary arteriole lumen/wall ratio was observed in both $PM_{2.5}$ groups. **Wet-to Dry Weight Ratio:** Significant increase in heart wet-to-dry weight ratio was observed in the 500 µg group.
Reference: Rivero et al. (2005, 088659) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 3 mo **Weight:** ~250 g	$PM_{2.5}$, collected from heavy traffic area in Sao Paulo, Brazil. $PM_{2.5}$ Composition (%): S (3.05), As (0.30), Br (0.21), Cl (2.09), Co (2.65), Fe (2.67), La (5.42), Mn (0.64), Sb (0.21), Sc (3.25), Th (8.14) **Particle Size:** $PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** 50 and 100 µg of $PM_{2.5}$. **Time to Analysis:** HR and SDNN were assessed immediately before instillation, 30 and 60 min post-instillation.	HR decreased significantly with time, but no significant effect of treatment or interaction between time and treatment was observed. In contrast, there was a significant SDNN interaction between time and treatment. The SDNN decreased 60 min after instillation with $PM_{2.5}$ concentration of 50 and 100 µg.
Reference: Seagrave et al. (2008, 191990) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 10-12 wk **Weight:** 250-300 g	GEE (2 1996 General Motors 4.3-L V6 gasoline engines; conventional Chevron Phillips gasoline, U.S. average composition) (CO, NO, NO_2, SO_2, THC) ($PM_{2.5}$ composition- EC, OC, SO_4, NH_4, NO_3) Simulated downwind coal emission atmospheres (SDCAs) (fly ash, gas-phase pollutants, sulfate aerosols, NO, NO_2, SO_2) Paved Road Dust (RD) (Los Angeles, CA; New York City, NY; Atlanta, GA) **Particle Size:** GEE: 150 nm (MMAD), RD: 2.6 ± 1.7 µm, SDCA: 0.1-1.0 µm	**Route:** Nose-only Inhalation **Dose/Concentration:** GEE: 60 µg/m^3, SDCAs: 317-1072 µg/m^3, RD: 306-954 µg/m^3; GEE: CO- 104 ppm, NO- 16.7 ppm, NO_2- 1.1 ppm, SO_2- 1.0 ppm, THC- 12ppm; SDCAs: CO- <1 ppm, NO- 0.19-0.62 ppm, NO_2- 0.10-0.37 ppm, SO_2- 0.07-0.24 ppm, THC- <1 ppm **Time to Analysis:** 6 h exposure. Cannula ligated into trachea and connected to rodent ventilator. Thorax and abdomen opened.	GEE produced CL in the lungs, heart, and liver. RD produced a significant effect in the heart at the low dose. SDCAs had no effect on CL. RD significantly increased the heart's oxidative stress, as demonstrated by the TBARS levels..

Reference: Sun et al. (2008, 157033) **Species:** Human **Cell Lines:** BEAS-2B; Vascular Smooth Muscle Cells (hSMCs); and Monocytes (THP-1)	Ambient Particles collected from Sterling Forest State Park, Tuxedo, NY (24 h/day for 4 wk) **Particle Size:** Particle size ranges: 1. <0.18 µm 2. 1.8 - 2.5 µm or 3. 2.5 - 10 µm	**Route:** In vitro **Dose/Concentration:** 10-300 µg/ml **Time to Analysis:** Doses were tested for durations up to 24 h.	Dose durations tested for up to 24-h did not indicate detectable effects on cell viability. **Effect of PM on TF Expression and Activity in hSMCs:** In the PM size range of 1-3 µm, significant increases in TF expression was observed at doses of 100 and 300 µm /mL. In the <0.18 µm size range, significant increase in TF expression was observed at all doses. The particles with sizes 0.18 - 1.0 µm did not induce significant change in TF expression. **Effect of PM on TF Expression and Activity in Monocyte Cells:** TF protein expression increased with <0.18 µm and the 1- 3 µm range particles. Expression was increased in the 0.18-1.0 µm particle range but it was limited compared to the other PM size ranges. In general TF expression was higher in monocytes than in hSMCs cells, but not significantly. **Effect on TF Expression and Activity in Bronchial Epithelial Cells:** 100 µg/mL of the 1-3 µm and <0.18 µm particles significantly increased TF expression. **TF mRNA Expression:** TF mRNA was increased rapidly within the first hour in response to SRM-1694a PM. The lowest dose of SRM PM_{10} µg/mL induced highest levels of mRNA in hSMCs, no further increase was observed at higher concentrations.
Reference: Sun et al. (2008, 157032) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 500-650 g	$PM_{2.5}$ or UFP **Particle Size:** $PM_{2.5}$; UFP: <0.1 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** Mean $PM_{2.5}$ concentration: 79.1 ± 7.4 µg/m^3. Normalized $PM_{2.5}$ over 10wk period: 14.1 µg/m^3. **Time to Analysis:** 6 h/day, 5 day/wk random exposure to $PM_{2.5}$, UFP, or FA for a total of 10 wk. At the end of wk 9 exposure, rats were infused w/ 0.75 mg/kg/day of AII for 7 days. $PM_{2.5}$, UFP, or FA, continued during AII infusion period. AII = angiotensin II	**Mean Arterial Pressure (MAP):** After AII infusion, MAP was significantly higher in $PM_{2.5}$ - AII vs. FA-AII group. Aortic Vasoconstriction to PE was potentiated with exaggerated relaxation to the Rho-kinase (ROCK) inhibitor Y-27632 and increase in ROCK-1 mRNA levels in the $PM_{2.5}$ - AII group. Superoxide production in the aorta was increased in the $PM_{2.5}$. AII group compared to FA-AII group, inhabitable by apocynin and L-NAME with coordinate upregulation of NAD(P)H oxidase subunits p22phox and p47phox and depletion of tetrahydrobipterin.
Reference: Sun et al. (2008, 157032) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 500-650 g **Cell Line:** Primary Rat Aortic Smooth Muscle Cells (RASMCs)	$PM_{2.5}$ or UFP **Particle Size:** $PM_{2.5}$; UFP: <0.1 µm	**Route:** Cell Culture **Dose/Concentration:** UFP, $PM_{2.5}$: 10 or 50 µg/mL; AII: 100 nmol/L **Time to Analysis:** Exposed to UFP or $PM_{2.5}$ and parameters measured at 0, 1, 3, 6, and 15 min. AII = angiotensin II	Exposure to UFPs and $PM_{2.5}$ was associated with an increase in ROCK activity, phosphorylation of myosin light chain, and MYPT1. Pretreatment with N-Acetylcysteine and the Rho kinase inhibitors (Fasudil and Y-27632) prevented MLC and MYPT-1 phosphorylation by UFPs suggesting a superoxide-mediated mechanism for $PM_{2.5}$ and UFPs effects.

Reference: Sun et al. (2009, 190487) **Species:** Mouse **Gender:** Male **Strain:** C57BL/6, c-fmsYFP (transgenic, yellow fluorescent protein under monocyte-specific promoter) **Age:** 8, 10 wk **Weight:** NR	PM (concentrated- northeastern regional background; Tuxedo Park, NY) **Particle Size:** 2.5 µm (diameter)	**Route:** Whole-body Inhalation. IT Instillation. **Dose/Concentration:** Exposure chamber (mean): 72.7 µg/m^3, IT: 1.6mg/kg **Time to Analysis:** C57BL/6 mice, fed high-fat chow 10wk. Exposed in vivo 6 h/day, 5 day, 128 days. fmsYFP rendered diabetic or fed normal chow 10 wk. IT instilled with PM 2 times/wk for 10 wk.	**Metabolic Impairment:** PM induced insulin, homeostasis model assessment indexes, elevated glucose, and abnormalities in lipid profile consistent with the IR phenotype. **Vascular Endothelium:** PM decreased peak relaxation and ED50 to ACH and peak relaxation to insulin. Lower levels of NO release were seen. **Insulin Signaling:** PM reduced the phosphorylation of Akt in intact aorta. PKC-β11 was the only PKC isoform to increase. **Adipose Inflammation, Visceral Adiposity:** PM significantly increased TNF-α, IL-6, E-selectin, ICAM-1, plasminogen activator inhibitor-1, and restin. PM increased visceral and mesenteric fat mass. F4/80+ macrophages in fat tissue and adipocyte size increased. PM downregulated IL-10 and glactose-N-acetylgalactosamine-specific lectin. **YFP Cell Adhesion and Infiltration:** PM increased YFP cells in the adipose tissue, YFP cell infiltration in the mesenteric fat, and YFP cell adhesion to endothelium.
Reference: Tamagawa et al. (2008, 191988) **Species:** Rabbit **Gender:** Female **Strain:** New Zealand White **Age:** 12 wk **Weight:** Acute (average)- 2.4 ± 0.2 kg, Chronic (average)- 2.7 ± 0.3 kg	PM_{10} (urban; Ottawa, Canada) **Particle Size:**: 0.8 ± 0.4 µm (mean diameter)	**Route:** Intrapharyngeal Instillation **Dose/Concentration:** Acute- 2.6mg/kg, Chronic- 2mg/kg **Time to Analysis:** Acute animals exposed days 1, 3, 5. Chronic animals exposed 2 times/wk for 4 wk.	**Inflammation:** PM_{10} induced more macrophages, AMs, positive and activated AMs, and fewer tissue macrophages. NO, WBC and PMN were only significantly higher in the first two wk and IL-6 in the first wk. **Vascular endothelial function:** PM_{10} significantly reduced Ach-stimulated relaxation and did not alter SNP-stimulated relaxation. A significant inverse relationship between IL-6 and Ach-induced relaxation occurred at wk 1 in the acute model and wks 1 and 2 in the chronic model. **AMs:** The chronic model had a significant correlation between IL-6 and both positive and activated AMs at wk 1. A significant inverse relationship occurred between Ach and both the volume fraction of positive and activated AMs.
Reference: Tankersley et al. (2008, 157043) **Species:** Mouse **Gender:** Male **Strain:** C57BL/6, C3H/HeJ, B6C3F1 **Age:** 18, 28 mo **Weight:** NR	Carbon black (CB) (Wright dust feed particle generator-BGI, Waltham, MA) **Particle Size:** 0.1-1.0 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** Average $PM_{2.5}$ concentration- 401 ± 46 µg/m^3, Average PM_{10} concentration- 553 ± 49 µg/m^3 **Time to Analysis:** 3 h/day, 4 days	**Hemodynamics:** CB significantly elevated right atrial and ventricular pressures, pulmonary arterial pressure and vascular resistance, all of which were more pronounced in the 28 mo-old mice. RV contractility (specifically, the ejection fraction and maximum change in pressure over time) reduced in CB-exposed 28 mo-old mice. **Heart Tissue:** CB significantly declined Ca2+-dependent NOS activity and was more pronounced in 28 mo-old mice, who also had NOS2 upregulated. CB enhanced ROS generation and NOS-uncoupling and was greatest in 28 mo-old mice. CB also increased MMP-2, MMP-9, ANP, BNP, which were greatest in 28 mo-old mice. CB also reduced PKG-1 in 28 mo-old mice.

Reference: Tankersley et al. (2007, 097910) **Species:** Mouse **Gender:** Male **Strain:** C3H/HeJ and C57BL/6J **Age:** 10 wk **Weight:** 22-26 g	Carbon Black (CB) **Particle Size:** CB: 2.4 µm (MMAD) (GSD 2.75 µm).	**Route:** CB: Whole-body Inhalation; Sympathetic (S) & Parasympathetic (PS) blockade: IP Injection **Dose/Concentration:** CB: 159 ± 12 µg/m^3; PS (atropine): 0.5 mg/kg; S(propanolol): 1 mg/kg **Time to Analysis:** Successive 3 h CB and FA Exposures: conducted from 9 a.m. to 1 p.m., or at least 3 h after dark-to-light transition (exposure period selected based on the nadir in circadian pattern in HR responses). Subgroups of both strains exposed to PS & S blockade.	**FA Exposure with Saline:** A significantly greater 3 h average response occurred in C3 compared with B6 mice. **PS Blockade:** No evident strain difference between C3 and B6 was observed. **S Blockade:** 3 h average HR responses for C3 mice were significantly reduced compared with saline. **CB Exposure:** HR responses were significantly elevated in C3 compared with B6 mice, but these HR responses were not different relative to FA exposure. **S Blockade:** HR was significantly elevated in B6 mice during CB relative to FA, but was not changed in C3 mice.
Reference: Tankersley et al. (2004, 094378) **Species:** Mice **Strain:** AKR/J **Age:** ~180 days	Carbon Black (CB) and Filtered Air (FA) **Particle Size:** CB: 0.1 to 1 um.	**Route:** Whole-body Inhalation **Dose/Concentration:** CB average concentration: 160 ± 22 µg/m^3 **Time to Analysis:** FA exposure on day 1, CB exposure 3 h/day for 3 consecutive days (days 2-4)	On day 1, HR was significantly depressed during FA in terminally senescent mice. By day 4, HR had significantly slowed due to the effects of 3 days CB exposure. The combined effects of terminal senescence and CB exposure acted to depress HR to an average (± SEM) 445 ± 40 bpm, ~ 80 bpm lower compared to healthy HR responses. The change in rMSSD was significantly greater on day 1 and day 4 in terminally senescent mice, compared to healthy mice. LF/HF ratio was significantly depressed in terminally senescent mice on day 1. By day 4, significant increases in LF/HF were evident in healthy mice during CB exposure. Terminally senescent mice modulated a lower HR without change in the LH/HF ratio during CB exposure.
Reference: Thomson et al. (2005, 087554) **Species:** Rat **Gender:** Male **Strain:** F344 **Weight:** 200-250 g	Urban Ambient Particles (EHC-93) from Ottawa, Canada; O_3 **Particle Size:** Respirable Modes (aerodynamic diameter): 1.3 and 3.6 µm. Non-respirable Mode (aerodynamic diameter): 15 µm	**Route:** Nose-only Inhalation **Dose/Concentration:** EHC-93: 0, 5, 50 mg/m^3; O_3: 0, 0.4, 0.8 ppm **Time to Analysis:** 4 h to particles, O_3, or combination of particles and O_3.	Both pollutants individually increased preproET-1, ET-1 and endothelial NOS mRNA levels in the lungs shortly after exposure, consistent w/ the concomitant increase in plasma of ET-1[1-21]. Prepro-ET1 mRNA remained elevated 24 h post-exposure to particles but no after O_3. Both pollutants transiently increased ET-B receptor mRNA expression, while O_3 decreased ET-A receptor mRNA levels. Coexposure to particles plus O_3 increased lung preproET-1 mRNA but not plasma ET-1[1-21], suggesting alternative processing or degradations of endothelins. This coincided w/ an increase of MMP-2 in the lungs (this enzyme cleaves bigET-1 to ET-1[1-32]).
Reference: Thomson et al. (2006, 097483) **Species:** Rat **Gender:** Male **Strain:** F344 **Weight:** 200-250 g	Urban Ambient Particles (EHC-93) from Ottawa, Canada; O_3 **Particle Size:** NR	**Route:** Nose-only Inhalation **Dose/Concentration:** EHC-93: 0, 50 mg/m^3; O_3: 0, 0.8 ppm **Time to Analysis:** 4 h to particles, O_3, or combination of particles and O_3. Sacrificed immediately following exposure or following 24 h recovery.	Circulating levels of both ET-1[1-21] and ET-3[1-21] were increased immediately after exposure to PM and O_3. While expression of preproET-1 mRNA in the lungs increased, expression of preproET-3 mRNA decreased immediately after exposure. PreproET-2 mRNA was not detected in the lungs, and exposure to either pollutant did not affect plasma ET-2 levels. Coexposure to O_3 and particles, while altering lung preproET-1 and preproET-3 mRNA levels in a fashion similar to O_3 alone, did not cause changes in the circulating levels of the two corresponding peptides.

Reference: Totlandsdal et al. (2008, 157056) **Species:** Rat **Gender:** Male **Strain:** WKY/NCrl and Crl: WI (Han) **Age:** Adult **Weight:** Crl/WI, 250-300 g **Use:** Isolation of Rat Ventricular Cardiomyocytes and Cardiofibroblasts (RVCMs and RVCFBs)	Pigment Black Printex 90 (Frankfurt, Germany); PM: SRM 1648 **Particle Size:** Printex 90: 12-17 nm; PM: NR	**Route:** Cell Culture **Dose/Concentration:** Printex 90: 0, 50, 100, 200 or 400 µg/mL; PM: 0, 200 µg/mL **Time to Analysis:** 20 h	**Cardiac Cell Cultures**: IL-6 release was strongly enhanced upon exposure to conditioned media, and markedly exceeded the response to direct particle exposure. IL-1, but not TNF-α, seemed necessary, but not sufficient, for this enhanced IL-6 release. The role of IL-1 was demonstrated by use the use of an IL-1 receptor antagonist that partially reduced the effect of the conditioned media, and by a stimulating effect on the cardiac cell release of IL-6 by exogenous addition of IL-1 α and IL-1 β.
Reference: Tzeng et al. (2007, 097883) **Species:** Rat **Strain:** Wistar Kyoto **Cell Type:** Primary Vascular Smooth Muscle Cell Culture (VSMCs): isolated from thoracic aortas from 200-250 g rats.	Motorcycle Exhaust Particulate Extract (MEPE) collected from a Yamaha motorcycle with a 50 cm^3 two-stroke engine using 95% octane unleaded gasoline. **Particle Size:** PM_1, $PM_{2.5}$, PM_{10}	**Route:** In vitro **Dose/Concentration:** 10-100 µg/mL **Time to Analysis:** 3 days	Exposure of VSMCs to MEPE (10-100 µg/mL), enhanced serum-induced VSMC proliferation. The expression of proliferating cell antinuclear antigen was also enhanced in the presence of MEPE. VSCMs treated with MEPE induced increase COX-2 mRNA, protein expression, and PGE2 production, whereas the level of COX-1 protein was unchanged. MEPE increased the production of ROS in VSMCs, in a dose-dependent manner. MEPE triggered time-dependent ERK1/2 phosphorylation in VSMCs which was attenuate by antioxidants (NAC, PDTC). The level of translocation of NF-κB-p65 in the nuclei of VSMCs was also increased during MEPE exposure. The potentiating effect of MEPE in serum-induced VSMC proliferation was abolished by COX-2 selective inhibitor NS-398, specific ERK inhibitor PD98059, and antioxidants (NAC, PTDC).
Reference: Tzeng et al. (2003, 097247) **Species:** Rat **Strain:** Wistar Kyoto **Cell Type:** Primary Vascular Smooth Muscle Cell Culture (VSMCs)	Motorcycle Exhaust Particulate Extract (MEPE) collected from a Yamaha motorcycle with a 50 cm^3 two-stroke engine using 95% octane unleaded gasoline. **Particle Size:** NR	**Route:** In vitro **Dose/Concentration:** MEPE: 10 µg/mL; Nifedipine: 10 µmol; Manganese Acetate: 100 µmol; Staurosporine: 1-2 nM; Chelerythrine: 1 µm **Time to Analysis:** 18 h	MEPE induced a concentration-dependent enhancement of vasoconstriction elicited by phenylephrine in the organ cultures of intact and endothelium-denuded aortas for 18h. Nifedipine, manganese acetate, and staurosporine, but not chelerythrine, inhibited the enhancement of vasoconstriction by MEPE. ML-9 inhibited the enhancement of vasoconstriction by MEPE. MEPE enhanced the phosphorylation of 20k-Da in rat vascular smooth muscle cells. N-acetylcysteine significantly inhibited the enhancement of vasoconstriction by MEPE. A time-dependent increase in ROS production by MEPE was also detected in primary cultures of VSMCs.
Reference: Upadhay et al. (2008, 159345) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 6 mo **Weight:** NR	Ultrafine Carbon Particles (UFCP) **Particle Size:** Size- 31 ± 0.3 nm, MMAD- 46 nm, Surface area concentration- 0.139 m^2 particles/m^3, Mass specific surface area- 807m^2/g	**Route:** Whole-body Inhalation **Dose/Concentration:** 172 µg/m^3 **Time to Analysis:** Acclimatized 2 day. 1 day baseline. 24 h exposure. 4 recovery. Sacrificed 1st or 3rd day of recovery.	**Cardiophysiology:** The mean arterial BP and HR increased but returned to baseline levels by the 4th recovery day. SDNN and HRV decreased. RMSSD and LF/HF decreased but were not significant. **Pulmonary Inflammation:** UFCP did not cause pulmonary inflammation. **Pulmonary and Cardiac Tissue:** HO-1, ET-1, ETA, ETB, TF, PAI-1 significantly increased in the lung on the 3rd recovery day. HO-1 was repressed in the heart, but the other markers had slight, nonsignificant increases. **Systemic Responses:** Neutrophil and lymphocyte cell differentials significantly increased on the 1st recovery day. Other blood parameters were unaffected. The plasma renin concentration increased on the first 2 recovery days. Ang I and II concentrations increased on the 1st recovery day but was not significant.

Reference: Wallenborn et al. (2008, 191171) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 13 wk **Weight:** NR	Zinc Sulfate ($ZnSO_4$, aerosolized) **Particle Size:** NR	**Route:** Nose-only Inhalation **Dose/Concentration:** 9.0 ± 2.1 µg/m^3, 35 ± 8.1 µg /m^3, 123.2 ± 29.6 µg /m^3 **Time to Analysis:** Exposed 5 h/day, 3 days/wk, 16 wk. Half of the rats used for plasma/serum analysis, other half for isolation of cardiac mitochondria.	A trend toward increased BALF protein was seen. Cardiac mitochondrial ferritin had a small, significant increase. Mitochondrial succinate dehydrogenase and glutathione peroxidase had small, significant decreases. Subchronic exposure to 100 µg/m^3 caused expression changes of cardiac genes involved with cell signaling events, ion channels regulation, and coagulation. No pulmonary-related effects were seen.
Reference: Wallenborn et al. (2007, 156144) **Species:** Rat **Gender:** Male **Strain:** WKY, SH, and stroke-prone SH (SHRSP) **Age:** 12-15 wk	PM: precipitator unit power plant residual oil combustion **Particle Size:** PM: 3.76 µm (bulk) ± 2.15	**Route:** IT Instillation **Dose/Concentration:** WKY vs SHRSP: 1.11, 3.33, 8.33 mg/kg SH vs SHRSP: 3.33, 8.33 mg/kg **Time to Analysis: Single,** 24 h Note: 4 h post-exposure study done on WKY vs SHRSP but not published.	**Oxidative Stress - Cardiac:** SOD increased in the SHRSP vs WKY experiment only. Only SHRSP at 8.33 mg/kg showed a significant increase when compared to the control. **GPx:** No action but SHRSP levels were similar to SHR and, in the WKY vs SHRSP experiment, SHRSP exhibited higher activity level than WKY. **Ferritin:** Equivocal results were observed. Levels decreased at the high dose for WKY and SHRSP but increased at medium doses for SH and SHRSP. **ICDH:** Levels increased for WKY and decreased for SHRSP.
Reference: Wellenius et al. (2003, 055691) **Species:** Dog **Gender:** Female **Strain:** Mixed mongrel **Age:** NR **Weight:** 14-17 kg	CAPs **Particle Size:** 0.26 ± 0.04 µm	**Route:** Permanent Tracheostomy **Dose/Concentration:** Median: 285.7 µg/m^3, Range: 161.3-957.3 µg/m^3 **Time to Analysis:** Thoracotomy and tracheostomy performed. 5-13 wk recovery. Pairs of subjects: exposed 6 h/day either 2nd or 3rd exposure time and filtered air other days. 5 min preconditioning occlusion. 20 min rest interval. 5 min experimental occlusion. Some dogs exposed 6 h/d, 4 days (consecutive), filtered air on day 4.	CAPs increased the ST-segment elevation and remained elevated 24 h after exposure. This increase was seen in precordial leads V4 and V5. Multivariate regression analyses showed that the mass concentration of Si was significantly associated with the peak ST-segment elevation and integrated ST-segment change. Univariate regression analyses showed Pb to also be significantly associated with these measures. CAPs had no effect on peak heart rate during occlusion or the maximum occlusion-induced increase in heart rate.
Reference: Wellenius et al. (2004, 087874) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** Adult **Weight:** ~250 g **Use:** Rat Model for Acute Myocardial Infarction (AMI): Left-ventricular MI induced. Animals allowed to recover for at least 12 h after surgery.	CAPs (Boston, MA); exposures during the period of 07/2000 and 01/2003. CO **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** CO: 35ppm; CAPs (median concentration): 350.5 µg.m^3; CAPs+CO: (CAPs median concentration): 318.2 µg/m^3 **Time to Analysis:** 1 h exposure to CAPs or CAPs+CO for 1 h. Exposure to pollutants was preceded and followed by 1 h exposure to FA.	CO exposure reduced the ventricular premature beat (VPB) frequency by 60.4% during the exposure time compared to controls. This effect was modified by both infarct type and the number of pre-exposure VPBs, and was mediated through changes in HR. Overall, CAPs exposure increased VPB frequency during the exposure period, but this did not reach statistical significance. This effect was modified by the number of pre-exposure VPBs. In rats with a high number of pre-exposure VPB, CAPS exposure significantly decreased VPB frequency (67.1%). Overall, neither CAPs nor CO had any effect on HR, but CAPs increased HR in specific subgroups. No significant interactions were observed between the effects of CO and CAPs.

Study	Pollutant	Exposure	Effects
Reference: Wellenius et al. (2006, 156152) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** Adult **Weight:** ~250 g **Use:** Rat Model for Acute Myocardial Infarction (AMI): Left-ventricular MI induced. Animals allowed to recover for at least 12 h after surgery.	CAPs: (Boston, MA) **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** CO: 35 ppm; CAPs (median concentration): 645.7 $\mu g.m^3$; CAPs+CO: 37.9 ppm **Time to Analysis:** CAPs or CAPs+CO exposure for 1 h. Exposure to pollutants was preceded and followed by 1 h exposure to FA.	Among rats in the CAPs group, the probability of observing supraventricular arrhythmias (SVA) decreased from the baseline to exposure and post-exposure periods. The pattern was significantly different than that observed for the FA group during the exposure period. In the subset with one or more SVA during the baseline period, the change in SVA rate from baseline to exposure period was significantly lower in the CAPs and CO groups only, when compared to the FA group. No significant effects were observed in the group simultaneously exposed to CAPs and CO.
Reference: Wichers et al. (2004, 055636) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 75 day	HP-12 (oil-combustion derived PM obtained from inside wall of a Boston power plant stack burning residual oil number 6). Water-leachable constituents (µg/mg): SO4 (217.3); Zn (11.4); Ni (6.9); Fe (0.0); V (1.3); Cu (0.2); Pb (0.0) 1M HCl-leachable constituents (µg/mg): SO4 (220.6); Zn (15.5); Ni (14.8); Fe (15.6); V (32.9); Cu (1.1); Pb (1.7) **Particle Size:** 3.76 µm (MMAD) (GSD 2.16)	**Route:** IT Instillation **Dose/Concentration:** HP-12 (mg/kg): 0.00 (saline control), 0.83 (low), 3.33 (mid), 8.33 (high) **Time to Analysis:** 96 h or 192 h post-instillation.	Exposures to mid and high-dose HP-12 induced large decreases in HR, BP, and body temperature. The decreases in HR and BP were most pronounced at night and did not return to pre-instillation values until 72 h (HR) and 48 h (BP) after dosing. ECG abnormalities (rhythm disturbances, bundle branch block) were observed primarily in the high dose group.
Reference: Wold et al. (2006, 097028) **Species:** Rat **Gender:** Female **Strain:** SD **Use:** Left jugular vein and right carotid artery were cannulated.	UFPs from either ambient air (UFAAs) or diesel engine exhaust (UFDGs); UFIDs from industrial forklift exhaust and soluble fraction UFID suspension, particle free (SF-UFID) **Particle Size:** UFAAs diameter ≤ 150 nm; UFDGs diameter ≤ 100 nm	**Route:** IV Infusion **Dose/Concentration:** UFDG (50 µg/m) **Time to Analysis:** Infused w/UFAA or UFDG. Monitored continuously for 1 h then sacrificed.	Infusion of UFDGs caused ventricular premature beats (VPBs) in 2 out of 3 rats. Ejection fraction increased slightly in rats receiving UFAA and was unchanged in the UFDG and saline groups.
Reference: Wold et al. (2006, 097028) **Species:** Rat **Gender:** Female **Strain:** SD	UFPs from either ambient air (UFAAs) or diesel engine exhaust (UFDGs); UFIDs from industrial forklift exhaust and soluble fraction UFID suspension, particle free (SF-UFID) **Particle Size:** UFAAs diameter ≤150 nm; UFDGs diameter ≤ 100 nm	**Route:** Lagendorff Heart Perfusion **Dose/Concentration:** UFDG (100 µg/2ml); UFID (12.5 µg/l in perfusate); SF-UFID (12.5 µg/l) **Time to Analysis:** Lagendorff 1: Treated w/UFDG. Lagendorff 2: Treated with UFID & SFUFID. Both experiments were monitored continuously for 1 h after injection.	UFDGs caused a marked increase in left-ventricular and end-diastolic pressure (LVEDP) after 30 min of exposure. UFIDs caused a significant decrease in left-ventricular systolic pressure (LVSP) at 30min after the start of infusion. This effect was absent when SF-UFID was studied.
Reference: Yatera et al. (2008, 157162) **Species:** Rabbit **Gender:** Female **Strain:** WHHL **Age:** 42 wk **Weight:** 3.2 ± 0.1 kg (avg)	EHC-93 from Ottawa, Canada **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** PM_{10} suspension: 5 mg EHC-93 in 1 ml saline **Time to Analysis:** Exposed 2 times/wk for 4 wk. Acute effects observed at 0.5, 1, 2, 4, 8, 12, and 24 h after initial instillation. Subchronic effects observed once/wk for 4 wk.	Exposure to PM_{10} caused progression of atherosclerotic lesions in thoracic and abdominal aorta. It also decreased circulating monocytes expressing high levels of CD31 and CD49 day, and increased expression of CD54 (ICAM-1) and CD106 (VCAM-1) in plaques. Exposure to PM_{10} increased the number of BrdU-labeled (*) monocytes into plaques and into smooth muscle underneath plaques.

Study	Pollutant	Exposure	Effects
Reference: Ying et al. (2009, 190111) **Species:** Mice **Gender:** Male **Strain:** ApoE$^{-/-}$ **Age:** 16 wk	CAPs:,New York City (Manhattan), NY; May-Sept 2007 **Particle Size:** $PM_{2.5}$	**Route: Whole-body** Inhalation **Dose/Concentration:** 138.4 ± 83.7 µg/m^3 **Time to Analysis:** 6 h/day, 5 day wk, 4 mo	**Vascular Tone:** Significant decrease in PE-induced maximum contraction of aortic rings in CAPs-exposed mice. No difference in sensitivity to PE between groups. Treatment with the soluble guanylate cyclase inhibitor ODQ restored the response to PE in CAPs aortic rings. No significant differences in relaxation induced by ACh. CAPs abolished the relaxation induced by Ca ionophore A23187. CAPs exposure slightly (but significantly) decreased maximum relaxation induced by SNP. **Protein Expression:** iNOS mRNA expression was increased in the aortas of CAPs-exposed mice. eNOS and GTPCH levels were unchanged. Distribution of inOS protein expression was limited to plaque in air-exposed mice and was found in the plaque and media for CAPs-exposed mice. **Superoxide Production:** Superoxide levels in CAPs-exposed mice were increased in the aorta compared to air-exposed mice. The addition of L-NAME significantly increased superoxide production. Extensive protein nitration in aortas of CAPs mice. NADPH subunits Rac1 and p47 phox mRNA expression was increased in aortas of mice exposed to CAPs. **Atherosclerosis:** Significant increase in plaque area of CAPs-exposed mice. Higher levels of macrophage infiltration, collagen deposition, and lipid composition of plaques from CAPs-exposed mice.
Reference: Yokota et al. (2004, 096516) **Species:** Rat **Gender:** Male **Strain:** SD **Weight:** 345-498.2 g	DEP (obtained from the Japan Automobile Research Institute) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** Group 1: DEP: 1 mg/0.1 ml; Group 2: DEP: 0.2 ml (10, 12.5 or 25 mg/ml); Group 3: DEP 2.5 or 5 mg/0.2 ml **Time to Analysis:** DEP pre-treatment 24-72 h before ischemia/reperfusion.	**DEP Effects on Mmyocardial Ischemia/Reperfusion-induced Arrhythmia:** An increased mortality was observed in the DEP group compared to the vehicle-treated group. 46% of the animals in DEP died during the first 3 min reperfusion period. The animals of other groups were intratracheally instilled with DEP at the beginning of ischemia/reperfusion experiment, or were pretreated with polyethylene glycol-conjugated SOD (1000 IU/kg, iv). In these animals, incidences of both arrhythmia and mortality were similar to those in the animals treated with the vehicle. **DEP Rffects on the Biochemical and Hematological Parameters:** Neutrophil count was elevated by a higher dose (5 mg) of DEP at 24 h after the IT instillation, and oxygen radical production, which was induced by 12-O-tetradecanoylphorbol 13-acetate, was enhanced at 72 h.
Reference: Yokota et al. (2005, 096003) **Species:** Rat **Gender:** Male **Strain:** SD **Weight:** 303-472.2 g	DEP from Japan **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** DEP: 5 mg/animal **Time to Analysis:** Single exposure 0.5, 1, 2, 3, 6, 12, 24, 48 h.	At 12 and 24 h post-instillation, circulatory neutrophil counts in the 5 mg DEP group were significantly elevated, and were 2.1-fold (12 h) and 2.3 fold (24 h) in vehicle treated animals. 1 mg DEP caused an increase of approximately 0.4-fold in CNC at 6 h. 12-O-tetradecanoylphorbol 13-acetate induced oxyradical production (ORP) in the isolated neutrophil was enhanced at 12 and 24 h after instillation with 5 mg DEP. In Serum, a marked elevation of CINC-1 and a slight elevation of MIP-2 were also observed, while TNF-α was not detected. GM-CSF was not detected in serum 24 h post-instillation.

Study	Pollutant	Exposure	Effects
Reference: Yokota et al. (2008, 190109) **Species:** Mouse **Gender:** Male **Strain:** ddy **Age:** NR **Weight:** 39.6-46.0 g	DEP (DMSC (dichloromethane soluble-component), RPC (residual particle-component)) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 5 mg/kg, 10 mg/kg **Time to Analysis:** DMSC and RPC extracted from DEP. Mice acclimatized 7 day . DEP, DMSC, or RPC instilled. BALF and blood obtained and G-CSF, GM-CSF, IL-6 measured 2, 4, 12, 24 h post-instillation.	**Inflammation:** At 5 mg/kg DEP increased the total cell and macrophage count. DEP or RPC increased neutrophils at 5 and 10 mg/kg. 10 mg/kg DEP or RPC increased macrophages at 4 h and decreased at 12 h. **Hematology:** Compared to 5 mg/kg DEP, RPC increased RBC, WBC, and neutrophils. 10 mg/kg RPC or DEP caused sustained increases in RBC, WBC, and neutrophils. **Cytokines:** 5 mg/kg RPC markedly increased G-CSF and IL-6. Other cytokine increases at this dose were transient. 10 mg/kg DEP increased IL-6 at 4 h, and DEP or RPC increased G-CSF and IL-6 at 12 h. DEP or RPC also increased IL-1β. **Myocardium:** Myocardial MPO activity significantly increased in 5 mg/kg RPC at 12 and 24 h. Myocardial MIP-2 increased the most in 5 mg/kg RPC, while LIX tended to be lowered by RPC.

Table D-2. Respiratory effects: in vitro studies.

Study	Pollutant	Exposure	Effects
Reference: Aam and Fonnum (2007, 155123) **Species:** Human, Rat **Tissues/Cell Types:** Human-Neutrophil Granulocytes (NG); Rat- AM	DEP: SRM 1975 **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** NG: 8.8 - 280 µg/mL AM:140, 280 µg/mL Vitamin E = 5 µM **Time to Analysis:** 1 h	**ROS of NG:** Formation of ROS in NG decreased with increased doses of DEP. Lucigenin chemiluminescence of ROS formation diminished 25% at 8.8 µg/mL DEP and luminol chemiluminescence 32% with 17.5 µg/mL DEP. DCF fluorescence required much higher doses of DEP. Controls without PMA stimulation had highly reduced lucigenin and luminol with DEP dose of 140 µg/mL while DCF increased 116%. **ROS of AM:** 280 µg/mL of DEP decreased ROS level by 19% with DCF. DEP with PMA-unstimulated cells increased 24% with DCF. **Necrosis:** NG cell death was DEP dose-dependent. At 280 µg/mL, cell death increased 5.4% as compared to control. LDH concentration increased 1.6% with 70 µg/mL DEP and 3.9% with 280 µg/mL after 1 h.
Reference: Agopyan et al. (2003, 056065) **Species:** Human **Tissues/Cell Types:** BEAS-2B, NHBE, SAEC	PC: synthetic carboxylate-modified particles **Particle Size:** 2, 10 µm	**Route:** Cell Culture **Dose/Concentration:** PC2 = 0.83 g/mL or $3.4x10^9$ particles/mL PC10 = 0.8 g/mL or $3x10^6$ particles/mL **Time to Analysis:** PC2 = 12, 24, 8 h PC10 = 2, 6, 12, 24 h	**Calcium Imaging:** PC10 induced increase of Ca^{2+} concentration in all capsaicin-sensitive cells 100%. Similar reaction observed in cells exposed to PC2. However, more than 3-PC2s were required to induce a Ca increase unlike PC10. CPZ (10um) and amiloride could fully block PC-induced response. **cAMP:** Post 6 h, a dose-dependent increase in cAMP was observed. Again, CPZ blocked increase by 70-90% depending on cell type: SAEC >NHBE ~ BEAS-2B. **Apoptosis:** PC10 and PC2 induced apoptosis time-dependently. PC2 was slower in induction than PC10. Post 48 h, 80-95% cells were apoptotic in all cell types. Noncapaisin-sensitive cells (which did not bind to particles) did not exhibit apoptosis. CPZ reduced apoptosis by 97% BEAS-2B, 96% NHBE and 98% SAEC. Amiloride did not block apoptosis. **Necrosis:** Induction of necrosis by PC2 and PC 10 was negligible. A slight increase from 1% to 2% was observed at 24-48 h in NHBE and SAEC. BEAS-2B showed slight decrease from 3% to 4% in same time period.

Study	Pollutant	Exposure	Effects
Reference: Agopyan et al. (2004, 156198) **Species:** Human, Mouse **Tissues/Cell Types:** Human-NHBE, SAEC; Mouse-Wildtype and TRPV1(-/-) Terminal Ganglion Neurons (TG)	ROFA MSHA: Mt St Helen Ash **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 100 µg/mL ROFA or MSHA **Time to Analysis:** ROFA/MSHA in NHBE and SAEC = 2, 6, 24, 48 h ROFA/ MSHA in TG = 24 h cAMP measurements with NHBE and SAEC exposed to ROFA/MSHA = 6 h	**Calcium Imaging in NHBE and SAEC:** In 100% of reactive cells, ROFA/MSHA induced an increase in Ca^{2+}. Levels remained elevated as long as PM bound to plasma membrane. Washing and disjoining PM from membrane caused Ca^{2+} to slowly decline to baseline. CPZ (or CPZ and amiloride) reversibly inhibited PM-induced rises in Ca^{2+}. **Calcium Imaging in TRPV1(+/+) and (-/-) mice sensory neurons:** All sensitive neurons in TRPV1(+/+) increased Ca^{2+} in response to ROFA. No effect of ROFA in TRPV1(-/-). **cAMP:** ROFA and MSHA induced increases in Ca^{2+} in NHBE and SAEC cells, which was completely blocked by cAMP. **Apoptosis:** ROFA or MSHA induced time-dependent apoptosis, peaking at 24 h. CPZ again inhibited this response. Neurons bound to PM (<25um) induced apoptosis in TRPV1(+/+). Cells without bound PM or bound with PM (>25 µm) showed no effect. No apoptosis occurred in the absence of Ca^{2+}. **Necrosis:** Necrosis for any of the cell types was negligible. **PKA:** Inhibition of PKA resulted in 90+% apoptosis in NHBE and SAEC. Again, no apoptosis was observed in a Ca^{2+} free environment.
Reference: Ahn et al. (2008, 156199) **Species:** Human **Tissues/Cell Types:** A549	DEP: (6 cyl, 11L, turbo-charged, heavy-duty diesel engine, South Korea) Dex: anti-inflammatory (Sigma, St. Louis, MO) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentrations:** 0, 1, 5, 10, 50 and 100 µg/mL of DEP Some cells pre-treated with 10, 20, 40, 50 pg/mL of Dex. **Time to Analysis:** 24 h	**COX-2 Expression:** Cells expressed dose-dependent increases in COX-2 expression after treatment with 10-100 µg/mL of DEP. Treatment of 50 µg/mL for 24 h induced statistically significant COX-2 expression in both mRNA and protein levels. Pre-treatment with Dex significantly reduced expression of COX-2 mRNA and protein. Dex treatment induced dose-dependent suppression of DEP-induced protein levels. **PGE2 Levels:** Levels of the inflammatory mediator, PGE2, increased when were cells exposed to 50 µg/mL of DEP. Pre-treatment with 50 µg /mL Dex completely inhibited DEP-induced release of PGE2.
Reference: Ahsan (2005, 156200) **Species:** Human **Tissues/Cell Types:** Trx-1-transfected Clone of Murine L-929 cells; Control Clone (L-929-Neo1); A549	DEP: provided by Dr. Masaru Sagai, University of Health and Welfare, Aomori, Japan **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** DEP: 50 µg/mL hTrx-1- or L-929-Neo1: 40 µg/mL Pretreatment: rhTrx-1 (10 µg/mL) or DM-rhTrx-1 (NR) **Time to Analysis:** Pretreatment for 1 h. Parameters measured 3 h post exposure.	**ROS:** DEP induced significant increases of ROS in L929-Neo1 cells. hTRx-1 cells showed no affect. RT-PCR revealed hTrx-1 mRNA expression in transfected cells but not control L929-Neo1 cells. Endogenous murine Trx-1 mRNA expression increased in control cells, but not in hTrx-1 cells. A549 cells had increased ROS levels but these levels were suppressed with rhTrx-1 pretreatment. Pre-treatment with DM-rhTrx-1 increased ROS levels more. **Akt (antiapoptotic molecule):** Phosphorylated Akt prevents apoptosis. DEP induced phosphorylation of Akt in control cells after 3 h and dephosphorylation after 5 h. In hTrx-1 cells, Akt remained phosphorylated after 5 h. In A549 cells, Akt phosphorylated at 3 h and slowly turned off at 12-24 h. Pre-treatment with rhTrx-1 blocked dephosphorylation. This suggests that Trx-1 preserves active form of Akt and thereby protects against cytotoxicity from DEP.

Study	Pollutant	Exposure	Effects
Reference: Alfaro-Moreno et al. (2002, 156204) **Species:** Human, Mouse, Rat **Strain:** Human-A549; Mouse-J7 74A.1, BALB-c **Tissues/Cell Types:** HUVEC, Mouse Fibroblasts, Rat Lung Fibroblasts (RLF)	PM_{10}: Collected from 3 zones in Mexico City: North (industrial), Center (business) and South (residential) **Particle Size:** PM_{10}	**Route:** Cell Culture 15000 cells/cm^2 except: Cytotoxicity: Confluent Cultures 180,000 cells/cm^2. DNA Breakage: 20,000 cells/well. Cytokine Assays: 180,000 cells/cm^2 **Dose/Concentration:** Cytotoxicity: 10, 20, 40, 80, 160 µg/cm^2 Apoptosis: 160 µg/cm^2 DNA Breakage: 2.5, 5, 10, 20, 40 µg/cm^2 Cytokine Assays: 10, 20, 40, 80 µg/cm^2 E-Selectin Expression: 40 µg/cm^2 **Time to Analysis:** Cytotoxicity: 24, 48, 72 h; Apoptosis: 24 h; DNA Breakage: 72 h; Cytokine Assays: 24 h	**Cytotoxicity:** Cytotoxic effect exhibited dose-dependency after 72 h in proliferating cells of J774A.1, BALB-c and RLF cell lines. **Proliferating Cells:** Northern particles induced a statistically larger effect than central or southern particles. J774A.1 was more susceptible while BALB-c was less susceptible. A549 was most resistant to decreased viability during exposure. No significant variation in viability was observed when compared to the control. Particles were not cytotoxic among confluent cell growth for any cell lines when exposed to 20-160 µg/cm^2. **Apoptosis:** Overall, particles induced low rates of cell death via apoptosis. J774A.1 depicted similar levels of apoptosis when exposed to three PM zones, ~15% apoptotic cells measured. BALB-c was not reported. Results for the A549 measured apoptotic cells were: South- 4%, Central- 11% and North- 15%. HUVEC cells indicated an increase in apoptosis with northern particles. **DNA Breakage:** PM_{10} from all zones induced DNA breakage. A dose-dependent relationship was established with $PM_{2.5}$ particles at concentrations of 10 µg/cm^2. The Southern zone required a higher dose of PM (10 µg/cm^2) to produce the same effect as other zones (2.5 µg/cm^2). **Cytokines:** Particles induced TNF-α and IL-6 secretion in J774A.1 cells dose-dependently. IL-6 increased significantly with central particles. PGE2 secretion in RLF cells induced by exposure to PM showed dose-dependent responses. PM from the central zone induced the most PGE2 secretion. Max secretion was observed at doses of 40 µg/cm^2 from all three PM zones. **E-Selectin Expression:** HUVEC cells showed a 25% increase in E-selectin expression after exposure to 40 µg/cm^2 of PM.
Reference: Amakawa et al. (2003, 156211) **Species:** Mouse, Human **Strain:** Mouse-ICR **Tissues/Cell Types:** AMs **Gender:** Male **Age:** Mouse 6-7 wk; Human 20-24 yr	DEP (obtained from a 4JB1, Isuzu, 1500 rpm, 4cyl diesel engine) DEPE = DEP Extract (methanol) CB = Charcoal (Sigma) **Particle Size:** DEP- 0.4 µm, CB- 0.7 µm	**Route:** Cell Culture Mouse: 5×10^5 cells/mL; Human: 3×10^5 cells/mL **Dose/Concentration:** DEP = 1 or 10 µg/mL; DEPE = 1 or 10 µg/mL; CB = 1, 10, 100 µg/mL **Time to Analysis:** Human cells pre-treated with LPS 1 µg/mL. Murine cells pre-treated with SOD 300 IU/mL. Parameters measured 24 h post exposure.	**Cells:** For mice, more than 90% of the cells were macrophages and over 90% were viable. For humans, 96% of the cells were macrophages, 3% lymphocytes and 1% neutrophils; over 95% of the human cells were viable. **DEP Cytotoxicity:** None observed **Cytokines:** DEP (10 µg/mL) suppressed release of TNF-α and IL-6 for both mice and humans in a dose-dependent manner. Murine cells pre-treated with LPS or IFN-γ released even less TNF-α and IL-6. IL-10 was unaffected. Human macrophages pre-treated with LPS also released lower levels of TNF-α, IL-6 and IL-8. **ROS:** Pre-treatment of SOD on murine cells partially attenuated the suppressive effect of DEP as well as decreased the production of ROS generated by DEP (10 µg/mL). **Carbon:** Carbon particles did not suppress TNF-α or IL-6 release from murine AMs; however,100 µg/mL of CB stimulated TNF-α production. **Methanol:** No cytotoxicity nor cytokine release effects were observed. **DEPE:** DEPE suppressed TNF-α and IL-6 release in a similar way as DEP.

Study	Pollutant	Exposure	Effects
Reference: Amara et al. (2007, 156212) **Species:** Human **Cell Lines:** A549, NCI-H292	DEP = SRM 2975 CSC = cigarette smoke condensates (collected from Kentucky standard cigarettes, 2R4F; University of Kentucky) DC = DEP + CSC CB (Degussa, Frankfurt, Germany) **Particle Size:** CB: 95 nm; DEP: NR	**Route:** Cell Culture **Dose/Concentration:** DEP = 5-10 µg/cm^2 CB = 10 µg/cm^2 CSC = 10 µg/cm^2 **Time to Analysis:** 6 or 24 h	**Inflammatory Markers:** LDH of A549 was unaffected at either time point with DEP or CB. LDH increased with CSC at concentrations high than 10 µg/mL at both time points. DC had no effect. **Proteases:** MMP-1 mRNA expression showed a dose dependent increase with DEP in A549 cells. DEP also increased MMP-1 in NCI-H292 cells. CB and CSC had no effect. MMP-1 mRNA expressions were inhibited by N-acetylcysteine antioxidant. Similar inhibition was observed with NOX4 oxidase. DC induced a similar effect to DEP. MMP-1 protein expression increased post 24 h with DEP. MMP-2, TIMP-1, TIMP-2 mRNA expression was unaffected. **TGF:** TGF-β mRNA expression was unaffected. **ROS:** DEP and DC increased ROS formation after 1 h. DEP effect was inhibited by N-acetylcysteine antioxidant pre-treatment. **MAP-Kinase:** DEP induced MMP-1 expression increased ERK1/2 phosphorylation after 10 min, peaking at 30 min, and returning to normal levels at 60 min. Treatment with CBPs did not increase ERK1/2 phosphorylation whereas treatment with CSC resulted in phosphorylation. Only inhibitors of ERK1/2 reduced DEP induced MMP-1 activity. P38 and JNK inhibitors had no effect.
Reference: Anseth et al. (2005, 088646) **Species:** Human **Cell Lines:** A549; A549-p0 (lacking mitochondria)	s-ROFA: soluble portion **Particle Size:** 1.95 ± 018 µm	**Route:** Cell Culture (3X10^5 cells/mL) **Dose/Concentration:** 100 µg/mL **Time to Analysis:** Experiments conducted by spreading monolayer of Infasurf (calf lung surfactant extract on PBS, PBS+ROFA or conditioned media from A549 AEC. Parameters measured after one 6-h incubation period.	**Lung Surfactant Gelation:** ROFA alone and A549 conditioned media alone did not significantly alter Infasurf rheology. However, conditioned media from A549 AEC at 16 h induced a significant increase in elastic storage and viscous loss moduli. Inhibiting ROS production lowered effect, indicating s-ROFA gelation mediated through ROS. **ROS:** ROS mediated through mitochondria as evidenced by the effect of ROFA-AEC on surfactant gelation in the presence of mitochondria ROS inhibitors as well as A549-p0 cells.
Reference: Auger et al. (2006, 156235) **Species:** Human **Tissue/Cell Type:** Nasal Epithelial Cells	DEP: SRM1650 $PM_{2.5}$: obtained from a highway in Paris, France **Particle Size:** DEP: 400 nm (mean diameter); $PM_{2.5}$	**Route:** Cell Culture (2-3.5x10^4 cells/cm^2) **Dose/Concentration:** 10-80 µg/cm^2 **Time to Analysis:** Cells treated on apical side. Parameters measured 24 h following treatment.	**Cytotoxicity (LDH):** No cytotoxicity for DEP or $PM_{2.5}$ (80 µg/cm^2). **Cytokines:** In non-stimulated ALI cultures, IL-8 was the most abundantly secreted cytokine, followed by GM-CSF, TNF-α, and IL-6 in decreasing levels of production. Amphiregulin was moderately, but consistently, secreted. After treatment, both DEP and $PM_{2.5}$ induced IL-8 and amphiregulin release in a dose-dependent manner through the basolateral surface. $PM_{2.5}$ stimulated IL-6 and GM-CSF release through the apical surface. **ICAM-1 expression:** No effect from DEP or $PM_{2.5}$. **ROS:** DEP and $PM_{2.5}$ both increased ROS production in a dose-dependent manner.

Study	Pollutant	Exposure	Effects
Reference: Bachoual et al. (2007, 155667) **Species:** Mouse **Cell Type:** RAW 264.7	PM_{10} from two Paris, France subway sites: RER and Metro CB (Frankfurt, Germany) TiO_2 (Calais, France) DEP: SRM1650 (NIST) **Particle Size:** CB: 95 nm; TiO_2:150 nm; DEP: NR RER PM_{10}: 79% <0.5 µm, 20% 0.5-1 µm; Metro PM_{10}: 88% <0.5 µm, 11% 0.5-1 µm.	**Route:** Cell Culture (40,000 cells/mL) **Dose/Concentration:** All particles: 0.01, 0.1, 1, 10 µg/cm^2 **Time to Analysis:** 3, 8, 24 h	**Cell Viability:** No effects from any particulate at concentrations up to 10 µg/cm^2 for 24 h. **Inflammatory Effect:** Exposure of cells to 10 µg/cm^2 of RER or Metro induced time-dependent increase in TNF-α and MIP-2 protein release. This effect was similar to both locations. No effect was observed at low concentrations of PM_{10}. No effect of CB, TiO_2 or DEP was observed. **GM-CSF or KC production:** RER and Metro PM_{10} did not induce any effect at any concentration. **Effect on Protease mRNA Expression:** Exposure of cells to 10 µg/cm^2 RER or Metro PM_{10} did not modify mRNA expression of MMP-2 or -9 or their inhibitors TIMP-1 and -2. MMP-12 expression significantly increased after exposure to RER or Metro PM_{10} for 8 h. **Effects on HO-1 Protein Expression:** Exposure to 10 µg/cm^2 of RER or Metro PM_{10} for 24 h induced positive cytoplasmic staining for HO-1.
Reference: Baulig et al. (2007, 151733) **Species:** Human **Cell Line:** 16-HBE14o-	WUB: Winter Urban Background Particles (obtained from Vitry-sur-Seine, suburb of Paris, France) SUB: summer Urban Background Particles Vitry-sur-Seine) WC: Winter Curbside Particles, SRM1648 (obtained from Porte-d'Auteuil, ring road of Paris, France) SC: Summer Curbside Particles, SRM 1648 (Porte-d'Auteuil) DEP: SRM 1650a (NIST) DPL (control) **Particle Size:** WUB, SUB: $PM_{2.5}$; WC, SC, DEP: NR	**Route:** Cell Culture (20,000 cells/cm^2) **Dose/Concentration:** 10 µg/cm^2 **Time to Analysis:** 18 or 24 h	**EGF:** All native $PM_{2.5}$ induced similar AR secretion by bronchial epithelial cells (in decreasing order WC, WUB, SC, SUB), but this release was significantly greater than the release induced by DEP. β-cellulin increased with SC, WUB and WC. No data was available for SUB or DEP. **Interleukins:** IL-1α increased significantly with WUB, WC,SC, DEP, DPL (in decreasing order). No data was available for SUB. Exposure to WUB caused IL-1β to increase to induction factor of over 2. IL-11 R α decreased significantly with SUB. **Cytokines:** Exposure to WUB caused G-CSF to increase with an induction factor of over 2.Though not statistically significant, TNF-R1 also increased. **Proteases:** TIMP-2 decreased with WUB but significantly increased with SUB. Overall, SUB downregulated integrins and interleukins seen with other particles while upregulating neurotrophic factors, chemokine receptors and adhesion molecules. MMPs were not measured. **Chemokines:** CCR-3 significantly increased with SUB. GRO-γ and GRO-α increased with WC at both 18 and 24 h. DEP had no effect with GRO-α. Removal of metal from particles lowered response of GRO-α.

Study	Pollutant	Exposure	Effects
Reference: Bayram et al. (2006, 088439) **Species:** Human **Cell Type:** A549	DEP: (obtained from a 4JB1-type, light-duty, 4 cyl, 2.74-L Isuzu diesel engine) DEP-FCS: DEP + FCS DEP-NAC: DEP + N-acetylcystine, antioxidant DEP-A: DEP + AEOL10113, catalytic antioxidant DEP-S: DEP + SP600125, inhibitor of JNK DEP-N: DEP + SN50, inhibitor of NF-kB **Particle Size:** DEP: 0.4 µm (mean diameter)	**Route:** Cell Culture **Dose/Concentration:** DEP: 0, 5, 10, 50, 100, 200 µg/mL **Time to Analysis:** 24, 48, 72 h	**Cell Growth:** With 10% FCS (as a positive control), A549 cells exhibited time dependent growth. A mixture of FCS and DEP did not affect cell growth for up to 48 h. With DEP alone, cell growth was prevented from cell number reduction due to removal of serum at 48 and 72 h. A dose of 10 µg/mL induced a maximum proliferation effect. **Cell Cycle:** DEP increased the percentage of serum-starved cells in S phase at 48 h. DEP decreased the percentage in G0/1 phase and G2/M phase. **Apoptosis:** DEP prevented the increase in apoptotic, serum-starved cells. **Protein Expression:** p21CIP1/WAF1 expression increased at 48 h. DEP dose-dependently decreased this expression. **NAC:** NAC alone, at 33 mM, induced an increase in cell numbers. DEP-NAC inhibited cell numbers at 48 h. DEP-NAC inhibited cell numbers in S phase; thus, cells in G0/1 phase increased. DEP-NAC induced a further decrease of cells in G2/M phase. **AEOL10113:** DEP-A caused a dose-dependent decrease in cell numbers. **SP**600125**:** Alone, SP600125 increased cell numbers at 33 mM. DEP-S decreased cell numbers.
Reference: Becher et al. (2007, 097125) **Species:** Rat **Strain:** Crl/WKY **Cell Type:** AM, Alveolar Type II **Gender:** Male **Weight:** 200 g	SPM = suspended PM SRM-1648 **Particle Size:** 6-8 µm	**Route:** Cell Culture (1.5×10^6 cells/well AM; 6×10^6 cells/well Type II) **Dose:** 200 µg/mL = 20 µg/cm^2 **Time to Analysis:** 20 h	**Cytokines in Macrophages:** SPM increased TNF-α and MIP-2. NADPH inhibitor DPI reduced MIP-2 response, whereas iNOS inhibitor 1400W did not affect either. **Cytokines in Type 2 Cells:** SPM increased IL-6 and MIP-2 significantly. This SPM effect was inhibited by DPI, whereas1400W reduced the IL-6 response significantly. **ROS in Type 2 Cells:** SPM significantly increased ROS formation. DPI largely blocked this SPM effect. **ROS in Macrophages:** No significant increases were observed.
Reference: Becker et al. (2005, 088590) **Species:** Human **Gender:** Male and Female **Age:** 18-35 yr **Cell Types:** Alveolar Macrophages, NHBE	PM (Coarse, Fine, Ultrafine): Chapel Hill, NC **Particle Size:** PM-C: $PM_{2.5}$; PM-F: $PM_{0.1}$; PM UF: <0.1µm	**Route:** Cell Culture ($0.5\text{-}1\times10^5$ cells/well NHBE; $2\text{-}3\times10^5$/mL AM) **Dose/Concentration:** NH BE: 25, 50, 100, 250 µg/mL of PM; AMs: 50 µg/mL of DEP or 10 ng/mL of LPS **Time to Analysis:** 18h for NHBE; overnight for AMs	**Cytokines:** All 3 fractions induced dose-dependent increases in IL-8 secretion with PM-c, PM-F, PM-UF (in order of decreasing effects). TLR-2 antibody blocked these particle induced IL-8 effects. **Inhibitors of Endotoxin effects and TLR-4 activation:** No effects were observed in NHBE, but all 3 fractions repressed the IL-6 release in AMs. **TLR mRNA Expression:** PM did not affect TLR-2 mRNA in NHBEs. PM-C and PM-F induced a slight increase in TLR-4 mRNA in NHBEs while PM-UF induced a substantial increase. PM-C increased TLR-2 mRNA in AMs and decreased TLR-4 mRNA in AMs. **Induction of Hsp70:** PM-C and PM-F induced Hsp70 in NHBE dose-dependently. Hsp70 was not induced in AM following particle stimulator.

Study	Pollutant	Exposure	Effects
Reference: Becker et al. (2005, 088592) **Species:** Human **Gender:** Male **Age:** 18-35 yr **Cell Types:** AM, NHBE	PM (Coarse, Fine, Ultrafine): Chapel Hill, NC ROFA Fe, Si, Cr Components Oct 2001, Jan 2002, April 2002, July 2002 **Particle Size:** PM-C: 2.5-10 µm; PM-F: <0.1 µm; PM-UF: <0.1 µm	**Route:** Cell Culture (3-5×10^5 cells/well NHBE; 2-3×10^5 cells/mL AM) **Dose/Concentration:** NHBE: 11 µg/mL of PM; AM: 50 µg/mL of PM **Time to Analysis:** 18-24 h NHBE; 18 h AM	**IL-8 Release in NHBE:** PM-C and PM-UF induced effects. No effects from PM-F (all 4 dates). **IL-6 Release in AM:** All 3 fractions induced increase with later dates having generally lower effects. **ROS (DCF):** NHBE, at lower exposures, were observed to be more responsive to PM than AMs. AM exhibited highly variable results over time. **ROS (DHR):** NHBE cells were observed to be more responsive to PM than AMs. AM responsiveness to PM increased over 4 time periods; this was not observed in NHBE. **Seasonal Variability:** Coarse particles were more potent than F and UF regardless of the month, and the potency for PM to induce IL-6/IL-8 production varied significantly. Coarse particles induced a 5-25 fold change in IL-6 release for AMs and a 3-6 fold change in IL-8 release for NHBEs. **Metal Correlation to IL-6/8 induction:** Fe and Si were positively associated with IL-6 release in AMs incubated with the coarse fraction. Cr was positively associated with IL-8 release in NHBE cells incubated with F or UF.
Reference: Beck-Speier et al. (2005, 156262) **Species:** Human, Canine (Beagle) **Cell Types:** Human AMs, Canine AM (CAM)	DEP = SRM 1650a (NIST) EC = Ultrafine EC (spark discharge) P90 = Printex 90 (Carbon Black, Degussa) PG = Printex G (Carbon Black, Degussa) **Particle Size:** DEP: 20-40 nm; EC: 5-10 nm; P90: 14 nm; PG: 51 nm	**Route:** Cell Culture (1×10^6 cells/mL AM) **Dose/Concentration:** All particles: 1 (EC only), 3.2, 10, 32, 100 µg/mL **Time to Analysis:** 60 min	**Phagocytosis:** All particles were phagocytosed by CAM within 60 min. **Oxidative Potential:** EC showed a very high effect. DEP, P90 and PG had no effect **Formation of Lipid Mediators:** DEP, EC P90 and PG increased arachidonic acid and PGE2/TXB2 in CAM in a dose-dependent manner. Only EC increased LTB4 and 8-isoprostane. **ROS Activation:** All particles increased activity in canine macrophages with EC, P90 and PG increasing activity in a dose-dependent manner. DEP increased activity in canine macrophages. Similar results were observed human alveolar macrophages but only EC and P90 were tested. **Particle Mass vs Particle Surface Area:** PGE2/TXB2 effects were highly correlated with particle surface area.
Reference: Bitterle et al. (2006, 156276) **Species:** Human **Cell Type:** A549	C-UFP = ultrafine carbonaceous particles (obtained from a spark discharge aerosol generator GFG 1000, Palas, Karlsruhe, Germany) **Particle Size:** 90 nm (count median mobility diameter)	**Route:** Cell Culture (3×10^7 cells) **Dose/Concentration:** 44 ± 4 ng/cm^2; 87 ± 23 ng/cm^2; 230 ± 70 ng/cm^2 **Time to Analysis:** 6 h	**Cell Viability:** Exposure to clean air resulted in a 93.7 ± 9.1% viability. Exposure to low, mid and high doses of C-UFP resulted in a 94.9 ± 9.5% viability. Thus C-UFP had no effect on cell viability. **Interleukins:** Clean air controls induced a 2-3 fold increase in IL-6 and IL-8 production vs submersed control. U-CFP exposures induced a similar effect on IL-8 and IL-6 levels. **Antioxidant enzyme HO-1:** The mid dose increased transcription of HO-1 by 2.7 fold. There was no observed effect at the high dose level which indicates possible cytotoxicity.

Study	Pollutant	Exposure	Effects
Reference: Blanchet et al. (2004, 087982) **Species:** Human **Cell Type:** 16HBE	$PM_{2.5}$ (Vitry-sur-Seine, Paris, France) DEP = SRM 1650a CB = Carbon Black (Degussa) TiO_2 (Huntsman) **Particle Size:** CB: 95 nm; TiO_2: 150 nm	**Route:** Cell Culture (45,000 cells/cm^2) **Dose/Concentration:** All particles: 0.1, 1, 10, 30 µg/cm^2 **Time to Analysis:** 6, 18, 24, 30 h	**Amphiregulin Expression:** DEP and $PM_{2.5}$ both increased AR mRNA expression from 6 to 30 h, with $PM_{2.5}$ inducing higher expression levels than DEP. Both DEP and $PM_{2.5}$ increased AR protein secretion. No observed effect for CB and TiO_2. $PM_{2.5}$ induced protein secretion dose-dependently. **Signal Pathways in AR Secretion:** MAP kinase and tyrosine kinase inhibitors reduced effects of DEP and $PM_{2.5}$ but p38MAP kinase inhibitor did not. **Role of Oxidative Stress:** N-Acetylcysteine blocked AR secretion following $PM_{2.5}$. Antioxidant enzyme catalase had no effect. **Cytokines:** DEP induced a significantly high release of GM-CSF, higher than $PM_{2.5}$. EGFR antibody reduced GM-CSF release at 0.25 µg/mL dose.
Reference: Bonvallot et al. (2001, 156283), **Species:** Human **Cell Type:** 16HBE14o-	DEP: SRM 1650 OE-DEP: dichloromethane extract (2x) of DEP nDEP: native DEP sDEP: nDEP - OE-DEP CB: Carbon Black FR103 (Degussa) BaP: Benzo[a]pyrene CB: 95 nm NR **Particle Size:** CB: 95 nm; DEP: NR	**Route:** Cell Culture (3×10^6 cells) **Dose/Concentration:** DEP, sDEP, nDEP and CB = 10 µg/cm^2 OE-DEP = 15 µg/mL BaP = 0.25, 50 and 250 µg/mL **Time to Analysis:** 24 h	**Proinflammatory Response:** At 10 µg/cm^2, nDEP induced GM-CSF release by 4.7 fold. OE-DEP increased GM-CSF by 3.7 fold. BaP and sDEP also induced increases of CN-CSF but had smaller effect. CB had no effect. **NF-κB Activation:** nDEP and OE-DEP induced enhanced degradation of IκB at 2-4 h and 1 h respectively. NF-κB DNA binding was enhanced by OE-DEP (15 µg/mL, peak <1 h) and nDEP (10 µg/cm^2, peak at 2-h with plateau till 4 h). Both OE- and nDEP enhanced NF-kB DNA binding levels were higher than BaP enhanced binding levels. **CYP1A1 mRNA:** The CYP1A1 mRNA level was markedly increased in nDEP and OE-DEP treated cells in comparison with their respective controls. **Radical Scavengers (decreased ROS in situ):** Increases of GM-CSF and NF-κB DNA binding by nDEP and OE-DEP was attenuated by radical scavengers. **MAPK Activation:** Increases by nDEP and OE-DEP of GM-CSF was inhibited by Erk1/2 inhibitor but not by p38 inhibitors. Both nDEP and OE-DEP triggered Erk1/2 and p38 phosphorylation. sDEP affected p38 phosphorylation only.
Reference: Brown et al. (2007, 156300) **Species:** Human, Mouse **Cell Type:** PBMC, A549 (Human); J774A.1 (Mouse)	PM_{10} (London, England) CM from PM_{10}-treated human monocytes **Particle Size:** PM_{10}	**Route:** Cell Culture (1×10^6 cells/mL J774A.1; 5×10^6 cells/mL PBMC; 5×10^5 cells/well A549) **Dose/Concentration:** PM_{10}: 75 µl (10 µg/mL); CM: 250 µl; tBHP: 12.5 µm (in J774); TNF: 0, 500 pg, 1 ng, 10 ng **Time to Analysis:** tBHP:1, 2, 4 h; PM: 4 h; TNF: 18 h	**Cytokines:** PM_{10} induced release TNF-α protein from PBMCs at 10 µg/mL for 4 h. Further inhibited by verapamil and BAPTA-AM. Calmodulin inhibitor W-7 had no effect. CM increased IL-8 from A549 cells 3 fold. Verapamil, BAPTA-AM and W-7 significantly inhibited IL-8 release induced by CM. **ICAM-1:** A549 cells treated with TNF-α showed dose-dependently effect of TNF-α on ICAM-1 upregulation at 18 h. CM also induced upregulation. Verapamil, BAPTA-AM and W-7 fully inhibited CM-induced upregulation.

Study	Pollutant	Exposure	Effects
Reference: Calcabrini et al. (2004, 096865) **Species:** Human **Cell Type:** A549	$PM_{2.5}$ (Rome, Italy) **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture (5×10^4 cells/well) **Dose/Concentration:** 30, 60 µg/cm^2 (aliquot of 0.1 µg/µl) **Time to Analysis:** 5, 24, 48, 72 h	**Particle Characterization:** Components measured include C-rich particles, Ca sulfates, silica, silicates, Fe-rich particles, metals. Carbonaceous particles made up majority of PM. **Cell Surface Changes:** PM deposited on the cell surface showed dose and time-dependent increases in microvilli rearrangement and cell shape alterations without affecting apoptotic markers for up to 72 h. **PM internalization:** At 24 h with the low dose, aggregates of PM in cytoplasm or surrounded by membrane was observed. With the high dose, large particle aggregates often close to nuclear envelopes were observed. **Cytoskeleton:** At 72 h PM induced dose-dependent alterations from rearrangement/interweaving of microtubules to bundling of microtubules with some shortening/disruption. **Cell Growth:** PM decreased cell growth in a dose and time-dependent manner **ROS:** PM increased ROS at the high dose for 5 h but not at 24 h or with the low dose. **Cytokines:** PM induced TNF-α peaked at 5 h at high dose and 48 h at low dose, both ND at 72 h. PM induced IL-6 starting at 24 h thru 72 h in time and dose dependent manner.
Reference: Cao et al. (2007, 156322) **Species:** Human **Cell Type:** HAEC	NIST-DEP: collected using a diesel forklift and hot bag filter system. (NIST, Minneapolis, MN) C-DEP: obtained from a 30-kw (40 hp) four-cylinder Deutz BF4M1008 diesel engine (U.S. EPA) Organic extract fraction of particles NIST- DEP 2% C-DEP 20 % **Particle Size:** NR	**Route:** Cell Culture (5×10^5 cells) **Dose/Concentration:** NIST-DEP, C-DEP: 0, 12.5, 25, 50, 100, 200 µg/mL **Time to Analysis:** 1-4 h	**Cell Viability:** DEP had no effect. **Stat3:** Both DEPs induced time-dependent phosphorylization of Stat3 in cytoplasm. NIST-DEP induced phosphorylization dose-dependently from 12.5 to 50 µg/mL but stayed level at 100 and 200 µg/mL. p-Stat3 induction was inhibited by antioxidant BHA though it was reactivated with exposure to H_2O_2. Reaction induced by H_2O_2 was similar to that of DEP. **pStat3 Nuclear Transport:** NIST-DEP induced cytoplasmic pStat3 to move from cytoplasm into nucleus. **pEGFR Dephosphorylation:** After 4 h of NIST-DEP exposure, dephosphorylation was inhibited for up to 90 min.
Reference: Chang et al. (2005, 097776) **Species:** Human **Cell Type:** A540, THP-1	UfCB (Printex 90, Degussa) **Particle Size:** 14 nm	**Route:** Cell Culture (7×10^5 cells) **Dose/Concentration:** 100 µg/mL **Time to Analysis:** 4 h	**ROS in THP-1 and A549**: UFCB increased ROS. NAC pretreatment blocked most of the UFCB-induced ROS production. **VEGF in THP-1:** UFCB increased VEG. NAC decreased the UFCB effects below those of the control. **VEGF in A549:** Produced similar, but less marked, results as with THP-1.

Study	Pollutant	Exposure	Effects
Reference: Chauhan et al. (2004, 096682) **Species:** Mouse **Strain:** BALB/c **Cell Type:** RAW 264.7; J774A.1; WR19M.1	EHC-T: total EHC-93 (Env Health Ctr, Ottawa, Canada) EHC-I: insoluble EHC EHC-S: soluble EHC SRM1648: urban particulate St. Louis (NIST) SRM1649: urban dust/organics Washington (NIST) VERP: fine $PM_{2.5}$ (Vermillion, Ohio) Cristobalite: SRM 1879 (NIST) TiO_2: SRM 154b (NIST) **Particle Size:** EHC-93: 0.5 µm (median diameter); Cristobalite, SRM 1648, SRM 1649, TiO_2,: NR; VERP: $PM_{2.5}$	**Route:** Cell Culture (15000 cells/well) **Dose/Concentration:** Particle suspensions: 20, 50, 100 µg/well LPS: 0-5 µg/mL IFN-y: 0-1000 U/mL **Time to Analysis:** Particles added to culture at 0h, LPS and IFN-γ added at 2 h. Parameters measured after 22 h incubation period.	**Stimulation with LPS/IFN-y:** LPS and IFN-y each induced NO release. Combination of LPS and IFN-y produced larger effect in all cell lines. L-NMMA, NOS inhibitor, suppressed most of the NO production with 100 nmol/L. **Cellular Viability and Cytotoxicity:** Exposure of cells to particulates did not result in overt cytotoxicity or excessive loss of cellular material. There was no correlation between the cytotoxicity of the particles in the surviving cells and the loss of protein mass in monolayers. **Nitrite Production:** EHC-T, EH-93-I, SRM1648 and SRM 1649 produced dose-dependent decreases. Cristobalite only decreased at higher doses. No effect from EHC-S, VERP or TiO_2. **iNOS:** EHC-I, EHC-T, Crisobalite and SRM1648 inhibited iNOS expression. TiO_2 had no effect. EHC sol, SRM 1649 and VERP were not tested.
Reference: Chauhan et al. (2005, 155722) **Species:** Human **Cell Type:** A549	EHC-T: total EHC-93 EHC-I: insoluble EHC EHC-S: soluble EHC Cristobalite (SiO_2): SRM-1879 TiO_2: SRM-154b **Particle Size:** EHC-93: 0.4 µm (median physical diameter); TiO_2, SiO_2: 0.3-0.6 µm	**Route:** Cell Culture (150000 cells/flask) **Dose/Concentration:** All particles: 0, 1, 4, 8 mg/5ml **Time to Analysis:** 24 h	**Cellular Viability:** Decreased after exposure to EHC-T, EHC-I and cristobalite. Rate of reduction was not consistent across doses. EHC-S and TiO_2 had no effect on viability. **ET-1:** Release of ET-1 peptide decreased dose-dependently for EHC-T, -S and -I. Fractions of EHC-S and EHC-I were more potent than EHC-T. TiO_2 and Cristobalite also reduced ET-1 secretion although this was not consistent across the dose range. **Cytokines:** Results showed no detectable amounts of GM-CSF, IL-1β or TNF-α in cell culture supernatants. IL-8 increased dose-dependently with EHC-T, EHC-I and cristobalite. **VEGF:** VEGF significantly increased dose-dependently with EHC-T, EHC-S and cristobalite. EHC-S induced a significant decrease in VEGF. **Gene Expression:** mRNA levels for preproET-1 reduced at 24 h for all particle types. EHC-S induced a significant decrease in ET-1 expression at this high dose. ECE-1 mRNA expression increased with EHC-T and EHC-I. Other particles had no effect. ETaR mRNA increased with EHC-T, EHC-S, and TiO_2 in biphasic manner where the highest expression of mRNA was seen at the middle dose levels. EHC-S had no effect. ETbR mRNA increased with a low dose of EHC-T and decreased with a high dose of EHC-T. EHC-S, EHC-I and cristobalite induced an increase of ETbR. TiO_2 induced a significant decrease. **Proteases:** mRNA levels for MMP-2 reacted similarly to preproET-1. mRNA levels for TIMP-2 was significantly induced with EHC-I. EHC-T and EHC-S induced small effects.
Reference: Cheng et al. (2003, 156337) **Species:** Human **Cell Type:** A549	DEP-h: DEP with high sulfur DEP-LS: DEP with low sulfur GEP: gasoline engine exhaust particles Primed cells pretreated with TNF-α **Particle Size:** DEP-h: 15.9 nm; DEP-LS: 17.7 nm; GEP: 8.3 nm	**Route:** In Vitro Cellular Exposure (Exhaust flow-through cell culture with air-cell-interface, exhaust diluted 10-15x with 8×10^5 cells/mL) **Dose/Concentration:** DEP (total): 1.5-3.5×10^6 particles/cm^3; GEP (total): 1-2×10^6 particles/cm^3; TNF-γ: 5ml (25 ng/ml) **Time to Analysis:** 60-360 min	**IL-8:** DEP-h induced a 3 fold increase in IL-8 than that of the control. DEP-LS also induced increases. Primed cell cases had higher levels (10x) than unprimed when exposed to DEP-LS. DEP-h induced higher levels of IL-8 than DEP-LS. This response lasted for up to 6 h. GEP induced a statistically insignificant increase of IL-8 in unprimed cells. With primed cells, GEP induced levels of IL-8 that exceeded those of DEP-h and DEP-LS. This response lasted for 1-2 h.

Reference: Chin et al. (2003, 156340) **Species:** Rat, Human **Cell Line/Type:** RAW 264.7, MHS (Alveolar Macrophage Cell Line), A549	CB: (N339, with benzo[a]pyrene absorbed on surface. Manufactured in Cabot, Boston, MA) BaP Benzo [a] pyrene 1, 6-quinone: BP-1,6-Q (obtained from NCI, Kansas City, MO) **Particle Size:** CB 0.1 µm (mean diameter)	**Route:** Cell Culture **Dose/Concentration:** CB: 1, 2, 4 µg/mL BaP: 2 µg/mL BP-1,6-Q: 1 µM **Time to Analysis:** 1-24 h	**HO-1 mRNA Expression:** In RAW264.7, HO-1 mRNA levels increased with 2 and 4 µg/mL at 2 h. Increases continued to 8 h and declined by 24 h. BaP had no effect. BP-1,6-Q increased HO-1 mRNA after 1 h and was maintained until 8 h. In A549 and MHS, HO-1 mRNA increased after 1 h, peaking at 8 h in A549 and 4 h in MHS. **HO-1 Protein Expression:** An increase of protein was observed from 4-8 h in RAW264.7. **AP-1:** Increases in binding activity were observed in RAW 264.7 cells at 2 h.
Reference: Churg et al. (2005, 088281) **Species:** Rat **Strain:** SD **Weight:** 250 g **Cell Type:** Epithelial Cells of Tracheal Explants	EHC93 (Ottawa Urban Air Particles) TiFe = Iron-loaded fine TiO_2 (obtained from Aldrich Chemicals, Milwaukee, WI) **Particle Size:** EHC-93: 3-4 µm (MMAD); TiFe: 0.12 ± 1.4 µm (geometric mean diameter)	**Route:** Cell Culture **Dose/Concentration:** EHC-93, TiFe: 500 µg/cm^2 **Time to Analysis:** 1, 24 h. Some experiments (referred to as 2 h) explants transferred to different dish and incubated for additional hour. Pre-treated with Inhibitors/Chelators for 2 h.	**Activation of NF-κB:** Both particle types increased nuclear translocation of NF-κB. TiFe and EHC-93 increased NF-κB 1.5 fold at 1 h. TiFe increased NF-κB 3.5 fold at 2 h. EHC-93 increased NF-κB more than 2 fold. TiO_2 by itself did not increase NF-κB at any exposure duration. **Morphological changes in tracheal epithelial cells:** No evidence of dust particles was observed (EHC-93 or TiO_2) in the epithelial cell cytoplasm at 2 h. No evidence of morphologic cell damage from particles was observed. **Colchicine:** Treatment with colchicine did not prevent NF-κB activation. **Inhibitors/Activators:** Tetramethylthiourea (TMTU) (membrane-permeable active oxygen scavenger), Deferoxamine (redox-inactive metal chelator), PPS (Src inhibitor) AG1478 (epidermal growth factor receptor inhibitor) prevented NF-κB activation in both EHC93 and TiFe exposed-cells. Iron-containing citrate extract of both dusts increased NF-κB activation in both EHC93 and TiFe exposed-cells.
Reference: Courtois et al. (2008, 156369) **Species:** Rat **Strain:** Wistar **Cell Line:** Dissected intrapulmonary arteries from rats used in corresponding in vivo experiments	PM (SRM 1648) (63% in, 4-7% , mass fraction >1%: Si, S, Al, Fe, K, Na) UF carbon black (FW2, P60) **Particle Size:** SRM 1648 mean diameter 0.4 µm; ultrafine carbon black: FW2- 13 nm, P60- 21 nm	**Route:** Cell Culture **Dose/Concentration:** 100, 200 µg/mL **Time to Analysis:** 24 h incubation	**NO:** Generally, Ach-induced relaxation in intrapulmonary arteries decreased, Ach-induced cGMP accumulation decreased, and relaxation by SNP or DEA-NO also decreased. UF carbon black did not affect NO responsiveness. **Oxidative Stress, Inflammatory:** Dexamethasone prevented SRM 1648-induced impairment of the Ach relaxation response but antioxidants did not. TNF-α, MIP2, IL-8 increased. ROS was not affected.
Reference: Dagher et al., (2007, 097566) **Species:** Human **Cell Type:** L132 (Normal Lung Epithelial Cells)	LC10, LC50 = $PM_{2.5}$ (collected Jan-Sept in Dunkerque, France) **Particle Size:** cumulative frequency: 0.5 µm: 34%; 1 µm: 64%; 1.5 µm: 79%; 2 µm: 87%; 2.5 µm: 92%; 5 µm: 98%; 10 µm: 100%	**Route:** Cell Culture (3×10^6, 1.5×10^6, 0.75×10^6 cells/20mL) **Dose/Concentration:** LC10: 19 µg/mL; LC50: 75 µg/mL **Time to Analysis:** 24, 48 or 72 h	**p65 Protein:** Phosphorylation of p65 increased in PM-exposed L132 cells in dose-dependent manner. **IκBα Protein:** Phosphorylated IκBα protein concentrations increased in cytoplasm with both particle types at all time points. **p65 and p50 DNA:** p65 DNA binding increased at 24 h with LC10 and LC50, at 48 h with LC10, and at 72 h with LC10 and LC50. p50 DNA binding increased at all time points with LC10 and LC50.

Study	Pollutant	Exposure	Effects
Reference: Dai et al. (2003, 087944) **Species:** Rat **Strain:** SD **Weight:** 250 g **Cell Type:** Tracheal Explants	EHC-93 (Environmental Health Center, Ottawa) DEP: SRM 1650a (NIST) **Particle Size:** EHC-93: 3-4 µm (MMAD); DEP 1.55 ± 0.04 µm (CMD)	**Route:** Cell Culture **Dose/Concentration:** ECH, DEP: 500 µg/cm^2 **Time to Analysis:** Exposed for 1 h. Parameters measured following a 7 day incubation period.	**Hydroxyproline:** EHC93 induced an almost 3 fold increase in explant hydroxyproline. DEP increased tissue hydroxyproline 2.5 fold. **Procollagen:** EHC-93 doubled gene expression of procollagen. Procollagen gene expression could be fully inhibited by SN50, TMTU or treatment of the PM with DFX. Treatment of explants with p38 or ERK (inhibitors) had no effect on procollagen expression. DEP induced an increase in procollagen gene expression but this increase was completely prevented by SN50 and MAP kinase inhibitors (SB203580 and PD98059). Neither TMTU or DFX has any effect. **TGFβ1:** Treatment of explant with EHC93 approximately doubled gene expression for TGFβ1. Treatment with SN50, TMTU and fetuin (TGFβ antagonist) blocked increase. DFX, MAP kinase inhibitors (SB203580 and PD98059) had no effect. DEP roughly doubled TGFβ1 expression.SN50 and MAP kinase inhibitors (SB203580 and PD98059) fully blocked this effect. TMTU and DFX had no effect.
Reference: Doherty et al. (2007, 096532) **Species:** Rat **Strain:** NR8383 **Cell Types:** AMs	Ratios of: V: Fe; Al: Fe; Mn: Fe V = sodium vanadate ($NaVO_3$) Al = aluminum chloride hexahydrate ($AlCl_3$) Mn = manganese chloride tetrahydrate ($MnCl_2$) Fe = ferric chloride hexahydrate ($FeCl_3$) Ratios based on $PM_{2.5}$ measurements from NYC, LA and Seattle **Particle Size:** Metals from $PM_{2.5}$ samples	**Route:** Cell Culture (2×10^5 cells/mL) **Dose/Concentration:** Fe = 16 µmol (equivalent to urban NYC 500 µg $PM_{2.5}$); V and Mn tested in molar rations of 0.02 to 0.4 relative to Fe; Al tested in molar ratios of 0.125 to 8 relative to Fe. **Time to Analysis:** 20 h	**IRP:** Addition of V increased IRP activity 5 to 9 fold. Though there was no seeming dose responsivity, IRP activity remained strongly elevated over the range of V:Fe ratios tested. Addition of Mn only resulted in an effect at 0.1 molar ratio (two-fold), not at higher or lower ratios. Al resulted in peak increases of 5 fold at molar ratios 2 while declining to 2 fold at molar ratios 4 and 8. **Cytotoxicity:** Al was cytotoxic at molar ratios of 4 and 8. All other Al, V, Mn ratios had no effect. **Mixtures:** The combination of metals tested at NYC PM ratios and V drove all the Fe transport activity. Combinations of V+Mn and V+Al increased activity more than V:Fe alone.
Reference: Doornaert, et al. (2003, 156410) **Species:** Human **Cell Line/Type:** 16HBE14o-; P-HBE	DEP: SRM 1650 (NIST) CB: (Sigma, France) DPC: Dipalmitoyl phosphatidylcholine (positive control) 0.5 um **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** DEP and CB: 1-100 µg/mL **Time to Analysis:** Parameters measured 24, 48, 72 h post exposure. 1-HBE Cell Deadhesion Capacity: 24 h, evaluation of detachment performed every 5min for 40 min after. Cell Wound Repair Capacity: 24 h, repair evaluated 3.5, 7, 24 h after.	**Cytotoxicity:** DEP was cytotoxic at 100 µg/mL at all time points in a time-dependent manner. CB and DPC cytotoxicity was substantially lower but significant at 72 h. **Phagocytosis:** 1-HBE cell levels that were in contact with DEP or CB or have phagocytized those particles increased in a dose-dependent manner. DEP induced greater levels of cell contact and phagocytosis than CB. **F-actin:** Only DEPs were engulfed by F-actin stained cell fragments. **Actin CSK Stiffness:** DEP (5, 20, 100 µg/mL) induced net dose-dependent decrease in cytoskeleton stiffness and a dose-dependent decrease in actin cytoskeleton stiffness. CB produced no significant decrease. **Adhesion Molecules**: DEP induced a concomitant reduction of both CD49 (α3) and CD29 (β1) integrin subunits and a decrease in level of CD44 (HBE cell-cell and cell-matrix adhesion molecule) at both 20 and 100 µg/mL. **Proteases:** DEP also induced an isolated decrease in MMP-1 expression without change in tissue inhibitor of TIMP-1 or TIMP-2 at 100 µg/mL. CB produced no change or insignificant results. **1-HBE Cell Deadhesion Capacity:** DEP exposure induced a dose-dependent amplification of cell detachment at 5 min of incubation and onward. **Cell Wound Repair Capacity:** DEP inhibited wound repair/wound closure in a dose-dependent manner.

CSE and DEP had no effect. MM also had increased levels with asbestos, silica and MSU at high dose levels only. **Caspase-1:** Asbestos increased caspase-1 activity. **ROS:** Asbestos doses in THP1 exhibited an increase in ROS formation.
Reference: Doyle, et al. (2004, 088404) **Species:** Human **Cell Type:** A549 from non-smoking adults	BD: 1,3-butadiene, known carcinogen Acrolein: photochemical and NO product of BD in atmosphere Acetaldehyde: photochemical and NO product of BD in atmosphere Formaldehyde: photochemical and NO product of BD and ISO in atmosphere ISO: isoprene, 2-methyl analog of BD Methacrolein: photochemical and NO product of ISO in atmosphere Methyl vinyl ketone: photochemical and NO product of ISO in atmosphere **Particle Size:** NR	**Route:** Environmental Irradiation (smog) Chambers **Dose/Concentration:** 50 ppb NO; 200 ppbV ISO, BD **Time to Analysis:** Exposed to gases for 5 h. Analysis 9 h post exposure.	**Cytotoxicity:** ISO+NO and BD+NO induced small increases of LDH in A549. However, ISO+NO+light and BD+NO+light increased LDH levels 4-6 fold indicating photochemical products of ISO and BD are highly cytotoxic. LDH levels of each combination were equivocal. **IL-8 Protein:** Methacrolein, methyl vinyl ketone and formaldehyde (products of ISO) increased IL-8 protein levels significantly. ISO+NO had no effect. BD photochemical products (acrolein, acetaldehyde and formaldehyde) also increased IL-8 protein, more than doubling the photochemical products induced by ISO. BD+NO had no effect. **IL-8 mRNA:** IL-8 mRNA expression also increased with photochemical products of ISO and BD but did not reach a statistically significant level.
Reference: Duvall et al. (2008, 097969) **Species:** Human **Cell Type:** Airway Epithelial Cells	PM-F, -C, -UF Particles collected from: Seattle, WA (PM-S); Salt Lake City, UT (PM-SL); Phoenix, AZ (PM-P); South Bronx, NY (PM-SB); Hunter College, NY (PM-Sterling Forest, NY (PM-SF) **Particle Size:** Coarse: >2.5 µm; Fine: <2.5 µm; UFP: <0.1 µm	**Route:** Cell Culture (100,000 cells/cm^2) **Dose/Concentration:** 5 mg/ml **Time to Analysis:** 1, 24 h post exposure	**Particle Characterization:** PM-HR, PM-SL and PM-S contained the highest UF, F, and C concentrations. PM-SB and PM-HR had similar F and C concentrations. Sulfate was highest in PM-F for all sites except in PM-SB and PM-HR. Wood combustion was highest in PM-SL, PM-S, PM-P. Soil dust was highest in PM-SL and PM-S. **IL-8:** PM-UF induced a greater increase in IL-8 than other types of PM except PM-P. PM-UF is associated with vanadium, lead, copper, sulfate. PM-F-HR caused the greatest increase followed by PM-SB. PM-F-SF and PM-F-P was least effective. PM-C also caused an increase in IL-8 levels and was associated with vanadium and EC. **COX-2:** PM-F-S induced the greatest increase in COX-2 expression. Other PM-F sites induced similar increases. UF PM had no effect. PM-C, associated with EC, induced increases. **HO-1:** PM-F-SF induced the greatest increase in HO-1. PM-F-SL was the least effective. UF PM had no effect. PM-C, associated with copper, barium and EC, caused an increase.
Reference: Dybdahl et al. (2004, 089013) **Species:** Human **Cell Type:** A549	DEP: SRM 1650 (NIST) **Particle Size:** 90 nm (MMAD)	**Route:** Cell Culture (10^5 cells/mL) **Dose/Concentration:** 0, 10, 50, 100, 500 µg/mL **Time to Analysis:** 2, 5, or 24 h	**Cytokines:** DEP induced dose-dependent increases of IL-1α, IL-6, IL-8 and TNF-α at 24 h. Cytokines increased between 4 and 18 fold at the highest DEP dose as compared to controlled cells. DEP also increased IL-6 mRNA expression levels in a dose and time-dependent manner.IL-6 mRNA levels increased 14 fold at 24 h, 8 fold at 5 h, and 2 fold at 2 h. **Cell Viability:** DEP exposure did not decrease cell viability at any dose tested.

Reference: Fritsch et al. (2006, 156452) **Species:** Mouse **Cell Type:** RAW 264.7	$MAFO_2$: incinerator fly ash (collected by electrostatic precipitation in commercial municipal waste incinerator facility) composition representing 12% of total mass (mg/g): Fe (9.1); Pb (23.3); Zn (75.7); C (7.5) **Particle Size:** 165 nm (modal value)	**Route:** Cell Culture (1×10^6 cells/well) **Dose/Concentration:** 6.3-188 µg/cm^2 for Toxicity; 2.6, 6.5, 13.2 µg/cm^2 for Arachidonic Acid; 13.2 µg/cm^2 for MAPK Pathway; Other doses noted in Effect of Particles **Time to Analysis:** 1, 2.5, 5, 24 h	**Toxicity:** Viability decreased from 99% to 18% at 62.5-188 µg/cm^2. Lower doses had no effect. **Arachidonic Acid:** At 2.5 h, AA level increased 2 fold for 6.5 µg/cm^2 and 6 fold for 13.2 µg/cm^2. No increase was observed after 5 h. **MAPKs:** Cells pretreated with PD98059, an inhibitor of MEK-1, inhibited AA liberation due to $MAFO_2$ treatment of 13.2 µg/cm^2 **COX-2:** A time-dependent increase of COX-2 protein expression was exhibited at 2.5 and 5 h. **ROS:** A dose-dependent increase in ROS formation was observed at concentrations greater than 31.3 µg/cm^2 after 3 h. **GSH:** There was an observed increase of production at 20 h. Doses greater than 60 µg/cm^2 reduced total glutathione. **HO-1:** There was an observed dose-dependent increase in expression at 4 h.
Reference: Fujii et al. (2002, 036478) **Species:** Human **Cell Type:** HBEC (from current smokers), AMs, Co-Culture: AMs+HBEC **Age:** HBEC: 48-70 yr	PM_{10}: EHC-93 (Ottawa, Canada) **Particle Size:** PM_{10}	**Route:** Cell Culture (HBEC: 2.5-3× 10^6 cells/well); (AMs: 1.0×10^7 total) **Dose/Concentration:** 100, 500 µg/mL **Time to Analysis:** 2, 8, 24 h	**Viability:** Over 90% of HBEC were viable after a 24 h exposure of up to 500 µg/mL of PM. AMs incubated with and without 100 µg/mL saw no significant difference in viability. **Cytokine mRNA:** TNF-α, GM-CSF, IL-1β, IL-6, LIF, OSM and IL-8 mRNA expression increased in co-culture with 100 µg/mL at 2 and 8 h. In AMs, TNF-α, IL-1β, IL-6 mRNA expression increased with 100 µg/mL at 2 h. IN HBECs, IL-1β and LIF increased with 100 µg/mL at 2 h. HBECs added to AMs exposed to PM_{10}, further increase in mRNA of IL-1β, LIF and IL-8. **Cytokine Protein:** In co-culture and AMs, significant increase in protein production of GM-CSF, IL-8, IL-1β, IL-6 and TNF-α in dose-dependent manner. GM-CSF and IL-6 production significantly higher in co-culture then AM or HBEC alone. **Bone Marrow:** Co-culture instillation of supernatants increased circulating band cell counts at 6 and 24 h with 100 µg/mL.
Reference: Fujii et al.. (2001, 156455) **Species:** Human **Cell Type:** HBEC from current smokers **Age:** 48-70 yr	PM_{10}:EHC93 (Ottawa, Canada)99% <3.0um **Particle Size:** PM_{10}(99% < 3.0 µm)	**Route:** Cell Culture ($2.5\text{-}3\times10^6$ cells/dish) **Dose/Concentration:** 10, 100, 500 µg/mL **Time to Analysis:** 2, 8, 24 h	**Phagocytosis:** 18.6% of cells engulfed particles when exposed to 100 µg/mL. Over 90% remained viable. **Cytokine mRNA:** LIF mRNA increased dose-dependently at 2 h but declined at 8 and 24 h. GM-CSF increased dose-dependently at 8h and peaked at 24 h. IL-1α increased at 2 h, increased dose-dependently at 8 h and peaked at 24 h. M-CSF, MCP-1, IL-8 were unaffected. **Cytokine Protein:** LIF, GM-CSF, IL-1β and IL-8 increased dose-dependently. Soluble fraction of 100 µg/mL PM_{10} did not affect cytokine production.

Reference: Garcon et al. (2006, 096633) **Species:** Human **Cell Type:** L132	$PM_{2.5}$ (collected in Dunkerque, France for 9mo, Jan-Sept) **Particle Size:** $PM_{2.5}$- 0-0.5 µm (33.63%), 0.5-1.0 µm (30.61%), 1.0-1.5 µm (14.33%), 1.5-2.0 µm (8.69%), 2.0-2.5 µm (4.89%), >2.5 µm (7.87%)	**Route:** Cell Culture: 3×10^6 cells/20ml (24 h); 1.5×10^6 cells/20ml (48h); 0.75×10^6 cells/20ml (72 h) **Dose/Concentration:** 18.84, 37.68, 56.52, 75.36, 150.72 µg/mL; LC10- 18.84 µg/mL; LC50- 75.36 µg/mL **Time to Analysis:** 24, 48 or 72 h	**Cytotoxicity:** PM induced dose-dependent (R_2 =.9907) cytotoxic effect in proliferating L132 cells. **LDH:** Increase at 72 h with 56.52 and 75.36 µg/mL. **Oxidative Stress:** A decrease in MDF activity was observed at all exposure levels at 24, 48, and 72 h (72-h <5 % of control). MDA levels showed increase concentration after 72 h, both LC10 and LC50. LC10 and LC50 saw an increase in SOD activity at 24 h; LC50 saw a decrease in activity after 48 and 72 h. 8-OHdG and PARP exhibited increases at all time points with LC10 and LC50. **Inflammatory Response:** Increases of TNF-α concentration was exhibited at 24 h at LC50, and at 48 h and 72 h at LC10 and LC50. iNOS activity increase at all time points at LC10 and LC50.NO concentration exhibited increases at all time points after exposure to LC10 and LC50.
Reference: Geng et al. (2005, 096689) **Species:** Rat **Strain:** Wistar Kyoto **Tissue/Cell Type:** Lung macrophages	BPM: Blowing $PM_{2.5}$; PM collected from Wuwei City, Gansu Province, China (Blowing days correspond to desert storm days) NPM: Non-blowing (normal) $PM_{2.5}$ **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** 0, 33, 100, 300 µg/mL **Time to Analysis:** 4 h	**Cytotoxicity**: Dosages greater than 150 µg/mL decreased cell viability. **Plasma Membrane Fluidity**: Dose-dependent decrease had no effect on membrane lipid hydrophilic region. **Plasma Membrane Permeability**: LDH enzyme activity and extracellular AP activity increased dose-dependently, indicating increased membrane permeability, but this was only statistically significant at 300 µg/mL dose. NPM may affect some parameters at 100 µg/mL. Overall, NPM induced a slightly higher increase than BPM. **Intracellular Ca2+:** A dose-dependent increase was observed. **Lipid Peroxidation (TBA):** An increase was observed only at 300 µg/mL. **Antioxidant (GSH):** A decrease was observed only at 300 µg/mL.
Reference: Geng et al. (2006, 097026) **Species:** Rat **Strain:** Wistar Kyoto **Tissue/Cell Type:** Lung macrophages	DPM: dust storm samples; PM collected from Baotou City, Inner Mongolia, China in March 2004 NPM: normal PM **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** 0, 33, 100, 300 µg/mL **Time to Analysis:** 4 h	**Cytotoxicity**: MTT reduction assay revealed a significant decrease in cell viability at 150 µg/mL and 300 µg/mL. LDH enzyme activity significantly increased at 150 and 300 µg/mL. **GSH levels:** Significant decreases were seen in cellular GSH levels and increases in TBARS levels in both groups with a 300 µg/mL dose. **Plasma Membrane Activity:** In the plasma membrane, Na, K-ATPase were significantly inhibited. $Ca^{2+}Mg^{2+}$-ATPase were unaffected. **Plasma Membrane Lipid Fluidity**: Results indicate that DPM could increase the surface fluidity of membrane lipid. **Intracellular Ca2+:** A dose-dependent increase in free intracellular Ca2+ levels was observed.
Reference: Ghio et al. (2005, 088272) **Species:** Human **Cell/Tissue Type:** BEAS-2B	FAC: ferric ammonium citrate (component of ROFA) $VOSO_4$: vanadyl sulfate (component of ROFA) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 100 µM FAC - preexposed before metal compounds or oil fly ash 50 µM $VOSO_4$ - preexposed before metal compounds or oil fly ash 100 µg/mL ROFA **Time to Analysis:** 0-1 h, 4 h	**IRE DMT1:** FAC increased mRNA and protein expression for -IRE DMT1. $VOSO_4$ decreased mRNA and protein expression for -IRE DMT1. +IRE DMT1 unaffected by any treatment. **Metal transport:** Uptake of iron increased after pre-exposure to FAC and decreased after pre-exposure to $VOSO_4$. Pre-exposure to FAC again increase the uptake of both iron and vandium. $VOSO_4$ induced opposite effect, decreasing Fe uptake. **ROS:** Increased acetaldehyde, indicating increased oxidative stress. ROS decreased with FAC pretreatment. ROS increased with $VOSO_4$ pretreatment.

(2004, 057420) **Species:** Rat **Strain:** SD **Cell/Tissue Type:** AM	Coal Fly Ash MU = Montana Ultrafine MF = Montana Fine MC = Montana Coarse KF = West Kentucky Fine KC = West Kentucky Coarse Coal combustion using a laboratory-scale down-fired furnace rated at 50kW. Montana subbituminous coal and western Kentucky bituminous coal **Particle Size:** Coarse: >2.5 µm; Fine: <2.5 µm; UFP: <0.2 µm	**Route:** Cell Culture (2×10^5 cells/mL) **Dose/Concentration:** 125 µg/mL or 250 µg/mL **Time to Analysis:** 4 or 24 h	**LDH:** Mid and high doses of Montana ultrafine particles showed significant increase after 4 h exposure vs control. Other particle types had no effect. After 24 h, LDH level was not statistically significant between particles tested and control. **Cytokines:** Treatment with Montana ultrafine particles resulted in a significant production increase of TNF-α. MIP-2 showed increases in all the fine and ultrafine treatments, with Montana ultrafine and W. Kentucky fine PM showing the highest increases. IL-6 increased with Montana ultrafine particles although there was some variability and the increases were not statistically significant.
Reference: Gilmour et al. (2005, 087410) **Species:** Human **Cell/Tissue Types:** monocyte derived macrophages, HUVECs, A549, 16HBE	PM_{10}: Collected from the Marylebone and Bloomsbury monitoring sites in London, UK **Particle Size:** PM_{10}	**Route:** Cell Culture **Dose/Concentration:** 50 µg/mL **Time to Analysis:** 4 h, 6 h, 20 h	**IL-8**: PM_{10} at 50 µg/mL induced a significant increase in IL-8mRNA and protein expression in PMM and 16HBE at 6 and 20h. A less substantial increase was also observed in A549. **Procoagulant Activity**: PM_{10} induced a significant decrease in macrophage mediated clotting time in 16HBE. Other cell types were unaffected. **Annexin V Binding**: At 100 µg/mL, PM_{10} induced a significant increase in binding macrophages at 4 and 20 h. There was no effect at 50 µg/mL. **Tissue Factor mRNA Expression**: Expression was increased in macrophages at 6 h only. **tPA Expression**: mRNA expression decreased at 6 h. Protein expression decreased at 4 h and 20 h in a dose-dependent manner. **TF Expression:** TF mRNA expression increased in a dose-dependent manner at 6 h in HUVECs. Protein levels also increased at 4 h but declined to basal levels by 20 h.
Reference: Gilmour et al. (2003, 096959) **Species:** Human **Cell/Tissue Type:** A549	PM_{10}: Collected from the Marylebone and Bloomsbury monitoring sites in London, UK TSA H_2O_2 NAC Mannitol Provided by Sigma Chemical, Poole, UK or GIBCO-BRL, Paisley, UK **Particle Size:** PM_{10}	**Route:** Cell Culture **Dose/Concentration:** PM_{10}: 100 µg/mL; TSA: 100 ng/mL; $H2O_2$: 200 µM; NAC and Mannitol: 5 mM **Time to Analysis:** 24 h	**IL-8:** PM_{10}, TSA and $H2O_2$ treatment induced an increase of IL-8. Concomitant exposure of TSA with PM_{10} or H_2O_2 significantly increased IL-8 release when compared to PM_{10} or H_2O_2 alone. IL-8 mRNA expression with PM_{10} or H_2O_2 exposure and TSA coincubation caused significant increases. Silver staining of PCR products indicated that the IL-8 gene promoter was associated with acetylated H4 following TSA, PM_{10} and TNF treatment. **H4:** PM_{10} exposure significantly increased acetylation levels of H4 over controls. Increased acetylated H4 was mediated by PM_{10} in a dose-dependent manner. Treatment with PM_{10} and H_2O_2 increased HAT activity associated with H4 by 245% and 166% respectively. Significant increases in acetylation of H4 following treatment of cells with TSA, PM_{10} and H_2O_2 for 24 h was observed. PM_{10}induced HAT activity was significantly decreased in the presence of NAC and mannitol. Nuclear presence of HDAC2 protein was significantly reduced by exposure to both HDAC inhibitor and PM_{10}. There was a decreasing trend in HDAC2 gene expression following TSA and PM_{10} treatment. **NF-κB:** The activation of the transcription factor NF-κB was enhanced following the inhibition of HDAC with TSA and by treatment with

Reference: Graff et al. (2007, 156488) **Species:** Human **Cell/Tissue Type:** HAEC	PM -UF: ultrafine -F: fine -C: coarse Particles collected from Seattle, WA (-S), Salt Lake City, UT (-SL), Phoenix, AZ (-P), South Bronx, NY (-SB), Hunter College, NY (-H), Sterling Forest, NY (-SF) **Particle Size:** UF: <0.1 µm; F: 0.1- 2.5 µm; C: 2.5-10 µm	**Route:** Cell Culture **Dose/Concentration:** 250 µg/mL **Time to Analysis:** 6 h, 24 h	**Gene Expression:** PM-UF, PM-F, and PM-C both upregulated and downregulated genes in the HAECs though downregulation was far more common for all the three PM fractions. PM-F affected the greatest number of transcripts, followed by the UF and C fractions. **IL-8:** mRNA expression increased, with PM-F-S having the greatest impact. Aluminum, strontium, manganese and potassium were highly associated with expression. Wood combustion was moderately associated. **HOX-1:** mRNA expression increased, with PM-F-SF having the greatest impact. Potassium, manganese, strontium and wood combustion were highly associated with expression. Aluminum and vanadium were moderately associated.
Reference: Gualtieri et al. (2005, 097841) **Species:** Human **Cell Type:** A549	TD: Tire debris extracted in methanol, constituent of PM_{10} (generated by spinning a new automotive tire against abrasive surface) **Particle Size:** 10-80 µm	**Route:** Cell Culture **Dose/Concentration:** 10, 50, 60, 75 µg/mL **Time to Analysis:** 24, 48, 72 h	**Cytotoxic Effect:** Treated cells presented inhibitory effect on reduction of MTT which appeared to be dose and time-dependent. A statistically significant reduction was observed at 48 and 72 h. Trypan blue showed a significant PM lethality as well as a dose-dependent increase in mortality. **DNA Damage:** At 24 and 72 h, DNA damage increased dose dependently in damaged and ghost cells. **Cell Cycle Analysis:** At 24 h, TD extract-treated cells presented a significant increase in the percentage of cells in G1 phase when compared with control. This increase was associated with a decrease in the percentage of cells in S phase. At 48 and 72 h, the increase in percentage of cells in G1 was associated with a decrease in the percentage of cells in both S and G2/M phases. Cells exposed to TD extracts presented changed morphology. Modifications most obvious at 72 h. The highest dost produced increased vacuolization in cytoplasm and apoptotic nuclear images.
Reference: Hetland et al. (2005, 087887) **Species:** Rat **Gender:** Male **Strain:** Crl/Wky **Cell Type:** AMs	PMC = Coarse PMF = Fine -A = Amsterdam -L = Lodz -R = Rome -O = Oslo Coexposures PAH, Fe, Al, Zn, Cu, V **Particle Size:** PMC: 2.5-10 µm; PMF: 0.2-2.5 µm	**Route:** Cell Culture (1.5×10^6 cells/well) **Dose/Concentration:** 50, 100 µg/mL PM **Time to Analysis:** 20 h	**IL-6:** PMC from all cities exhibited increases in IL-6 release with spring and summer roughly equal and both inducing higher levels than the winter PMC. For the Spring and Summer samples, PMC-L exhibited the highest IL-6 releases (440% and 460% respectively) followed by Rome, A'dam/Oslo, and Oslo/A'dam. For the winter samples, Rome and Amsterdam induced higher IL-6 levels (340% and 300% respectively) than Lodz and Oslo (165% and 160%). The fine fractions did not induce any significant cytokine release. **TNF-α:** PMC from all cities increased TNF-α release with 50 µg/mL generally inducing a slightly higher increase than 100 µg/mL. **Constituent Correlation:** Levels of Fe, Al, Zn, Cu and V as well as PAH (total and fractions) showed no correlation with IL-6 release. **Endotoxin Correlation with IL-6 release:** A confirmatory test revealed no correlation.

Reference: Hetland et al. (2004, 097535) **Species:** Rat, Human **Cell Type:** Alveolar Macrophages (Rat), A549 **Strain:** Wky/NHsd **Gender:** Male **Weight:** 180-230 g	AMC = Ambient Coarse AMF = Ambient Fine AMUF = Ambient Ultrafine (AM samples taken at a suburban site, without a dominating PM source, near Utrecht, Netherlands) Road PM: PM_{10}, (collected in a road tunnel with predominating road abrasion due to use of studded tires in Trondheim, Norway) **Particle Size:** AMC: 2.5-10 µm; AMUF: <0.1 µm	**Route:** Cell Culture (1×10^6 cells/well) **Dose/Concentration:** 0, 100, 200, 400, 600, 800, 1000 µg/mL **Time to Analysis:** 20h (Type 2 cells); 40h (A549 cells)	**IL-8:** All 3 AM fractions showed dose-dependent increases in A549 cells until 600 µg/mL; at that concentration, levels declined. AMC showed the most pronounced decline which correlates with decreased viability. Road PM showed a near linear response until 1000 µg/mL, whereas DEP plateaued at 600 µg/mL in A549. **MIP-2:** AMC and AMUF had no effect on Type 2 cells. DEP induced increases at 200 µg/mL, whereas Road PM induced the strongest increase, peaking at 600 µg/mL in Type 2 cells. **IL-6:** AMC induced increases at 100 µg/mL in Type 2, but levels declined below normal at 200 µg/mL. AMUF induced a decline of IL-6 levels. Road PM induced significant increases in Type 2. DEP had a slight effect. AM fractions induced increases in A549 cells, peaking at 600 µg/mL with AMF. DEP and Road PM induced a dose-dependent increase. **Cell Survival:** AMC showed major effects at 200 µg/mL in Type 2. AMUF showed effects at 400 µg/mL. Road PM and DEP showed a gradual decline from 75% to 50% at 800 µg/mL in Type 2. All AM fractions induced a decrease in viability after 600 µg/mL in A549 with AMC inducing a larger decrease than AMUF and AMF; AMUF and AMF induced similar levels. Road PM and DEP had no effect on A549. **Apoptosis:** AMC elicited a marked induction of apoptosis 200 µg/mL in Type 2 cells. AMF showed a dose-dependent increase in A549. Other AM fractions showed some slight increases in both cell types. Statistical significance was reached for all particles except for Road PM.
Reference: Holder et al. (2008, 093322) **Species:** Human **Cell Type:** 16HBE14o	DEP: generated from a single cylinder diesel engine using , commercial certified #2 diesel fuel Copollutants: NO_X 7 ppm, CO_2 0.1% **Particle Size:** Suspension: 223 nm (mean diameter); ALI: 122 nm (mean diameter)	**Route:** Suspension (1×10^5 cells/cm^2), Air Liquid Interface (ALI, 1×10^5 cells/cm^2) **Dose/Concentration:** Suspension: 0.13, 0.24, 1.88, 2.5, and 12.5 µg/cm^2; ALI: 1 g/cm^3 (total number of particles: 2.3×10^7 particles/cm^2) **Time to Analysis:** Exposure for 6 h. Parameters measured 20 h post-exposure.	**ALI vs Tracheal Bronchial (TB) Deposition:** The TB region deposition is 1.5 nominally x ALI, but particle diameter deposited in the TB was 62 nm (geometric mean diameter) as compared to the particle deposition in the ALI, measuring 260 nm. **Inflammatory Response:** Suspended DEP decreased viability at concentrations of 2.5 µg/cm^2 or higher. IL-8 release (corrected for viability) increased at concentrations of 1.88 µg/cm^2 or higher in a dose-dependent manner. IL-8 exhibited intermediate levels of secretion between in vitro levels of 0.25 and 1.88 µg/cm^2. No statistically significant results were observed in ALI. Viability for ALI was near 100% (75% uncorrected).
Reference: Huang et al. (2003, 087376) **Species:** Human, Mouse **Cell Type:** BEAS-2B, RAW 264.7	PMC: PM coarse PMF: PM fine PMSM: PM submicron Collected between September-December 2000 from 4 ambient monitoring stations in Taiwan that represented background, urban, traffic, and industrial sites **Particle Size:** PMC: 2.5-10 µm; PMF: 1-2.5 µm; PMSM: <1 µm	**Route:** Cell Culture (5×10^5 cells/mL) **Dose/Concentration:** All PM: 50, 70, 100 µg/mL **Time to Analysis:** BEAS-2B: 8h; RAW 264.7: 16 h	**Viability:** None of the PM fractions affected cell viability. **IL-8:** Only PMSM induced a significant IL-8 increase in BEAS-2B. IL-8 response was associated with a combination of Mn and Cr (R_2 = 0.28). Response was also correlated with nitrate, although significance disappeared when 1 extreme nitrate value was removed. **Lipid Peroxidation:** Only PMSM enhanced lipid peroxidation in BEAS-2B, correlating with both elemental and . **TNF-α:** In RAW264.7, PMSM increased TNF-α production. Polymixin pretreatment significantly reduced TNF-α levels for all 3 PMs which indicates an endotoxin role in macrophage response. TNF-α production (after polymixin pretreatment only) was associated with Cr and Fe content.

Reference: Hutchison et al. (2005, 097750) **Species:** Mouse **Cell Line:** J774.1A	PM_{10}: Samples collected for 7 day during closure (-C) and reopening of steel plant (-R) PMT: PM total (aqueous sonicate) PMS: PM soluble aqueous PMI: PM insoluble aqueous **Particle Size:** PM_{10}	**Route:** Suspension **Dose/Concentration:** 500 µl (estimated concentrations of 112, 143, 156, 180, 233, 255 µg/1ml water) **Time to Analysis:** 4 h	**Particle Characterization:** Reopening of the plant showed a significant increase in the total and acid extractable metal content of PM. Aqueous extractable metal content did not change. Soluble zinc, copper and manganese also increased significantly post reopening. Iron was the most abundant in acid extractable metals and increased greatly at the reopening. **TNF-α:** PMT-R and PMT-C induced a statistically significant increase. Treatment with chelation agent reduced effect to control levels.
Reference: Imrich et al. (2007, 155859) **Species:** Rat **Gender:** Female **Age:** 12-14 wk **Cell Type:** AM	UAP: SRM 1649 (positive control) TiO_2: Particle control CAPs (Boston, MA) All cells primed with LPS Coexposure with NAC, dimethylthiourea (DMTU), $H2O_2$ or catalase **Particle Size:** CAPs: ≤2.5 µm; UAP: $PM_{2.5}$; TiO_2: ~1 µm	**Route:** Cell Culture ($2×10^5$ cells/well) **Dose/Concentration:** Caps 100 µg/mL; UAP: 50 or 100 µg/mL; LPS 250 ng/mL; NAC, DMTU: 2, 10, 20 mM; Catalase: 1, 5, 10 mM; H_2O_2 0-50 µm/hr **Time to Analysis:** 18-20h	**TNF-α:** DMTU at 20 mM reduced TNF in LPS-primed cells in control and UAP-treated groups. NAC at 20 mM reduced TNF release but this was not statistically significant. Catalase significantly inhibited TNF in control and UAP-treated groups. CAPs (especially the insoluble portion) significantly increased TNF unless co-exposed with NAC, DMTU or catalase. All three reduced levels back to around basal levels. DMTU was particularly effective at diminishing TNF release. H_2O_2 increased TNF release in CAPs-exposed cells. TiO_2 had no increased ability to induced cytokine release when mixed with H_2O_2. **Cell Death:** Viability decreased substantially when exposed to H_2O_2 + CAPs. The soluble fraction of CAPs showed to be more effective with H_2O_2 than the insoluble portion. TiO_2 had no significant effect. **NO:** Some CAPs induced slight increases when mixed with H_2O_2. No difference was observed between soluble and insoluble portions of CAPs. **DFO:** DFO at 0.05 mM completely inhibited oxidation induced with soluble CAPs + H_2O_2. Insoluble CAPs + H_2O_2 was also DFO-sensitive. DFO was ineffective against the insoluble CAPs induction of TNF and MIP-2.
Reference: Ishii et al. (2004, 088103) **Species:** Human **Cell Type:** A549 (collected from 6 lobectomy or pneumonectomy smokers), HBEC	EHC-93:PM_{10} (obtained from Environmental Health Directorate, Ottawa, Ontario, Canada) **Particle Size:** PM_{10}	**Route:** Cell Culture ($1×10^7$ cells) **Dose/Concentration:** 100 µg/mL **Time to Analysis:** 3, 6, 24 h	**Cytokines:** TNF-α, IL-1β, GM-CSF, IL-6, and IL-8 levels were significantly increased in A549 cells. **mRNA Expression:** MCP-1, ICAM-1 and IL-8 mRNA expression increased in untreated AM supernatants at 3 h. Only the MCP-1 levels were statistically significant at 3 h. Levels declined by 6 h. When A549 cells were exposed to PM_{10} exposed AM, levels of RANTES, TNF-α, ICAM-1, IL-1β, and LIF increased. Except for RANTES mRNA, these differences were less in the 6 h samples. VEGF increased as well, but this increase was not statistically significant. **TNF-α and IL-1β-neutralizing Antibodies:** IL-1β antibody alone or in combination with TNF-α significantly reduced expression of all eight mRNAs. Combinations for some mRNAs reduced expression by up to 1/2. This effect was not observed when A549 was treated with the control AM. **Transcription Factor Binding Activity:** Binding of AP-1 and Sp1 increased when A549 treated with supernatants from PM_{10}-exposed AM, but not from control AM.

Study	Pollutant	Exposure	Effects
Reference: Ishii et al. (2005, 096138) **Species:** Human **Cell Type:** AMs (obtained from 10 smokers who stopped smoking 6 wk prior), HBEC	EHC-93: PM_{10} (obtained from Environmental Health Directorate, Ontario, Canada) **Particle Size:** PM_{10}	**Route:** Cell Culture (HBEC: 2.5-3.0×10^6 cells; AM: 1×10^7 cells; co-culture of AM/HBEC: 5×10^6 cells) **Dose/Concentration:** 100 µg/mL **Time to Analysis:** 2, 24 h	**mRNA Expression After 2 h Exposure:** AM or HBEC exhibited no effect. In contrast, co-culture increased expression of MIP-1β, GM-CSF, M-CSF, IL-6, MCP-1 and ICAM-1-mRNA. **mRNA Expression After 24 h Exposure:** AMs exhibited no effect. HBEC increased levels of GM-CSf, LIF and ICAM-1. Co-culture, on the other hand, increased expression of MIP-1β, GM-CSF, M-CSF and ICAM-1 mRNA. **Protein Levels:** AM and HBEC both increased GM-CSF, IL-6 and MIP-1β release into the supernatant. Co-culture effect was not additive but synergistic (i.e., higher than expected). MCP-1 levels did not increase significantly. Co-culture appeared to decrease protein levels for both the control and PM values. M-CSF levels increased for co-culture only. **Surface Expression of ICAM-1:** Upon 24 h exposure to PM, HBEC exhibited an increase in expression. Expression in AMs were not affected by 2 h PM stimulation. **ICAM-1 Inhibitors:** IgG or anti-CD11b antibody was unaffected in co-culture.
Reference: Jalava et al. (2005, 088648) **Species:** Mouse **Cell Type:** RAW 264.7	UPM: SRM1649a (Washington, DC) DEP: SRM1650 (NIST) EHC-93: Ottawa dust (Environmental Health Center, Ottawa, Canada) HFP-00: Pooled ambient air $PM_{2.5}$ sample from Helsinki, Finland M-UPM: methanol extract of UPM **Particle Size:** SRM 1649a, SRM 1650, EHC-93: NR; HFP-00: $PM_{2.5}$	**Route:** Cell Culture (5×10^5 cells/mL) **Dose/Concentration:** 150 µg/mL **Time to Analysis:** Methanol treatment of PM samples: 24 h; Exposure to ambient PM samples: 2, 4, 8, 16, or 24 h.	**TNF-α:** All the PM samples increased TNF-α. **Cell Viability:** SRM1649a exhibited the most cytotoxicity, followed by HFP-00 and EHC-93. Methanol significantly affected cytotoxicity of the EHC-93 sample only. **Cytokines:** TNF-α concentrations in the cell culture medium significantly increased at all time points between 2 and 24 h. The highest increase was seen in EHC-93. IL-6 production also increased at different levels with the highest increase observed in EHC-93. No response was observed for IL-10. **Cell Viability:** Duration of exposures had no significant effect on any of the samples. A 2 h exposure time was sufficient to induce the typical reductions in cell viability.
Reference: Jalava et al. (2006, 155872) **Species:** Mouse **Cell Type:** RAW 264.7	PM: Collected east of Helsinki, Finland between Aug 23 and Sept 23, 2002 Divided in 12 groups (4 sizes by 3 exposure types): -S: seasonal average -W: wildfire -M: mixed -B: blank **Particle Size:** $PM_{10-2.5}$; $PM_{2.5-1}$; $PM_{1-0.2}$; $PM_{0.2}$	**Route:** Cell Culture (5×10^6 cells/mL) **Dose/Concentration:** 15, 50, 150 and 300 µg/mL **Time to Analysis:** 24 h	**Particulate Mass Concentrations in HVCL Size Ranges:** The largest increase of PM concentrations was observed in $PM_{1-0.2}$. **NO:** All 12 samples increased NO production when compared to corresponding unexposed controls. Peaks were observed at 150 µg/mL, except in $PM_{1-0.2}$. **Cytokines:** All 12 samples increased TNF-α and IL-6 production. $PM_{10-2.5}$ and $PM_{2.5-1}$ produced a much larger response than $PM_{1-0.2}$ and $PM_{0.2}$. IL-6 production for $PM_{0.2}$ was not measured. MIP-2 production also increased with similar trends. **Cytotoxicity:** All 12 samples induced dose-dependent decreases in cell viability. $PM_{10-2.5}$ were the least active inducers of apoptosis while PM0.2 showed the highest activity (4-17% of apoptotic cells).

Study	Pollutant	Exposure	Effects
Reference: Jalava et al. (2007, 096950) **Species:** Mouse **Cell Type:** RAW 264.7	Urban background PM PM_{10}, $PM_{2.5}$, and PM0.2 collected from 6 European cities during different times of the year from October 2002 to July 2003: -D: Duisburg (Fall) -P: Prague (Winter) -A: Amsterdam (Winter) -HR: Helsinki (spring), -B: Barcelona (spring) -AT: Athens (summer) **Particle Size:** PM_{10}: 2.5-10 µm; $PM_{2.5}$: 0.2-2.5 µm; $PM_{0.2}$: <0.2 µm	**Route:** Cell Culture (5×10^5 cells/mL) **Dose/Concentration:** 15, 50, 150, 300 µg/mL **Time to Analysis:** 24 h	**PM Characterizations:** The highest mass concentrations of PM_{10} and $PM_{0.2}$ were measured in Athens. Prague had the highest $PM_{2.5}$ concentrations. **NO:** All PM fractions induced statistically significant NO production in macrophages. $PM_{2.5}$ -P and $PM_{2.5}$ -AT produced significantly larger responses, though all samples at 150 and 200 µg/mL induced statistically significant production. When compared to the other $PM_{0.2}$ samples, -P and -HR produced significantly larger responses. **Cytokines:** PM_{10} showed average cytokine production to be 7.8 fold and 83 fold for TNF-α, and 4.4 fold and 530 fold for MIP-2 when compared to $PM_{2.5}$ and $PM_{0.2}$ respectively. PM_{10} induced statistically significant increases in production of TNF-α, MIP-2 and IL-6. $PM_{2.5}$, with exception of Prague, caused significant increases in cytokines. $PM_{0.2}$-A and -AT showed small yet statistically significant increases in TNF-α. An increase in MIP-2 was observed with -P and -HR. IL-6 increased significantly with PM_{10} and slightly with $PM_{2.5}$. In the $PM_{0.2}$ range, only the -A and -AT samples caused a small, statistically significant TNF- α production. MIP-2 production was only detected from the -P and -HR samples. $PM_{0.2}$ effects on IL-6 response were negligible. **Cytotoxicity:** The average cytotoxicity of PM_{10} and $PM_{2.5}$ were roughly equal, but $PM_{0.2}$ were less cytotoxic with the exception of -P. The dose-response trends for most of the samples were linearly declining, with PM_{10} and $PM_{2.5}$ exhibiting statistically significant declines in viability.
Reference: Jimenez et al. (2002, 156610) **Species:** Human **Cell Type/Line:** A549, THP-1, Mono Mac 6 (DSMZ)	PM_{10}: Collected from London and Edinburgh air particulate monitoring stations. TiO_2: Tioxide Europe (London, UK) and Degussa-Huls (Cheshire, UK) $UFTiO_2$: Tioxide Europe (London, UK) and Degussa-Huls (Cheshire, UK) **Particle Size:** PM_{10}, TiO_2: 200 nm; $UFTiO_2$: 20 nm	**Route:** Cell Culture (110,625 cells/well) **Dose/Concentration:** PM_{10}, TiO_2, $UFTiO_2$: 100 µg/mL; TNF-α: 10 ng/mL **Time to Analysis:** 4 h	**NF-κB and AP-1 DNA Binding**: NF-κB DNA binding increased in PM_{10} and TNF-α exposed macrophages by 9.5 and 12 fold. NF-κB activity remained unaltered in TiO_2 and $UFTiO_2$ exposed macrophages. **IL-8:** Cells treated with PM_{10} conditioned media increased transcription binding of NF-kB to IL-8 promoter sites. Increases were observed in gene expression after exposure to TNF-α and PM_{10}. TiO_2 or $UFTiO_2$ had no effect. Increases observed in IL-8 production with PM_{10}. **IL-8 Promoter CAT Activity:** PM_{10} media increased CAT expression by 65% over control. No differences observed with TiO_2 or $UFTiO_2$ media. **Neutrophil Chemotaxis:** PM_{10} conditioned media induced a 2.3 fold increase compared to control. **TNF-α and IL-1β Production:** PM_{10} media increased TNF-α and IL-1β production. No increases were observed in TiO_2 and $UFTiO_2$ media.

Study	Pollutant	Exposure	Effects
Reference: Jung et al. (2006, 132421) **Species:** N/A **Type:** Surrogate Lung Fluid	Soot Particles: Generated using a co-flow, laminar, diffusion flame system CB (Degussa) $PM_{2.5}$: Collected using IMPROVE air pollution samplers **Particle Size:** Soot: 185 nm; CB: 25 nm, $PM_{2.5}$	**Route:** Surrogate Lung Fluid **Dose/Concentration:** Soot: 0-30 mg; CB: 5-10 mg; $PM_{2.5}$: 50 or 100 µg/mL **Time to Analysis:** Parameters measured continuously over 2 h.	**OH Radical Formation:** Formation occurred with linear dependence on soot mass. Average response was 0.89 nmol OH produced per mg of soot. Formation also occurred with soot + hydrogen peroxide. Hydrogen peroxide alone did not form OH radicals. **Fe:** Average Fe concentration in soot particles was 305 ± 172 nM. Observed negative correlation between amount of Fe and amount of OH radical formation. DSF inhibited iron-induced increase in OH radical formation. **Carbon Black:** OH radical generation by carbon black was significantly less than soot. OH generation by CB was observed to be linearly proportional to PM mass, but CB was much less efficient at generating the OH radical. **$PM_{2.5}$:** A high variability in the increase of OH radicals was observed with $PM_{2.5}$. Pretreatment with DSF partially blocked OH radical production, but a significant level remained. This may be due to $PM_{2.5}$ containing high levels of Fe and Cu.
Reference: Kafoury and Madden (2005, 156617) **Species:** Mouse **Cell Type:** RAW 264.7	DEP: SRM 1975 (purchased from NIST, Rockville, MD) BAY11-7082, NF-κB inhibitor (coexposure) IL-1ß: obtained from Santa Cruz Biotechnology (Santa Cruz, CA) **Particle Size:** DEP: 0.3 µm (mean diameter)	**Route:** Cell Culture (3-4×10^5 cells) **Dose/Concentration:** DEP 25, 100, or 250 µg/mL; IL-1ß: 100 ng/mL **Time to Analysis:** DEP: 4 h pre-treated with BAY11-7082 for 1.5 h; IL-1β: 4 h	**TNF-α:** DEP induced a significant release of TNF-a at 100 and 250 µg/mL dose-dependently. Exposure at 25 µg/mL had no effect. IL-1β containing PM samples at 100 µg/mL also resulted in a significant release of TNF-α. **NF-κB Binding Activity:** Treatment of RAW 264.7 with BAY11-7082 significantly inhibited IL-1β-induced TNF-α release. Similar effects observed with DEP-induced TNF-α release. **Apoptosis:** Inhibition of NF-kB binding activity by BAY11-7082 resulted in DEP-induced apoptotic response. Without BAY11-7082, apoptosis was not induced even at the DEP dose of 250/µg/mL for 4 h. The control, U937 cells with campothecin, induced apoptosis.
Reference: Karlsson et al. (2006, 156625) **Species:** Human **Cell Type:** A549, Monocytes (isolated from heparinized whole blood)	PM (W1: wood burning in old-type boiler; W2: wood burning in modern boiler; P: wood pellets burning in pellets burner; T1: PM_{10} tire debris with studded tires and ABT pavement; T2a: PM_{10} tire debris with studded tires and ABS pavement; T2b: $PM_{2.5}$ tire debris with studded tires and ABS pavement; T3: PM_{10} tire debris with friction tires and ABS pavement; St: PM_{10} from busy street in Stockholm, Sweden; Su: PM_{10} from platform of subway station in Stockholm) **Particle Size:** W: NR, T1, T2a, T3, St, Su: PM_{10}, T2b: $PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** Suspension: 40 µg/cm^2; Culture: 100 µg/cm^2 (1 ml/well) **Time to Analysis:** Suspension: 4 h; Culture: 18 h	**PM Characterization:** Boiler emitting PM-W1 led to 4 times higher emission of particles when compared to PM-W2 and 8 times higher emissions when compared to PM-P. Total concentration and CO was substantially higher in the old-type wood boiler. **Effects with Filter Fibers:** No increase of DNA damage was observed compared to the water control. Filter fibers led to the induction of cytokines in human macrophages. **Genotoxicity:** All particulate samples induced DNA damage in A549 cells. PM-Su exhibited the most genotoxicity and induced 4-5 times more DNA damage than others. **Cytokines on Glass Fiber Filters:** PM-W2 induced a significant increase in IL-8. PM-St induced the highest increases of IL-6, IL-8, and TNF-α. **Cytokines on Teflon Filters:** PM-2a and PM-2b samples caused significant increases of IL-6, IL-8, and TNF-α.

Study	Pollutant	Exposure	Effects
Reference: Katterman et al. (2007, 096358) **Species:** Rat **Cell Type/Line:** RLE-6TN (Alveolar Epithelial Cell Line)	PM: Oils: OAAF, Oil Q, OII I II, NF2 PM: Coal Germany and Ohio Diesel particulates: ZODDA (doped with Zn), ZSDDA (doped with Zn and S): S: PMs washed in solution; F: Fresh samples; L: Leached Al_2O_3, Fe_2O_3, SiO_2, TiO_2, ZnO also tested **Particle Size:** NR	**Route:** Cell Culture (cytotoxicity: 50,000 cells/well; SEM: 25,000 cells) **Dose/Concentration:** Oils 0.2 mg/mL; Coals 0.7 mg/mL; Diesel 0.01 mg/mL; Al_2O_3 0.5 mg/mL; Fe_2O_3 0.7 mg/mL; SiO_2 0.7 mg/mL; TiO_2 0.7 mg/mL; ZnO 0.05 mg/mL **Time to Analysis:** 24 h	**Metabolic Activity:** For oils comprised of 3/4 fresh and 1/4 leached, metabolism decreased. Coals (fresh and leached) had no effect. ZODDA-F and ZSDDA-F both induced decreases in activity. ZSDDA-L had no effect. **Cellular Morphology:** PM-S had a minimal effect. PM-F induced widespread cell damage. **Constituent Differences between PM-F and PM-L:** In oil samples Cu, Ti and Ca salts were removed upon washing. Fe, Al, Si remained constant. **Grinding Effects:** Coal toxicity increased upon grinding, whereas diesel PM toxicity decreased upon grinding. **Metal Oxide Effects:** Only SiO_2, and ZnO (much higher at lower concentrations than other metal oxides) decreased metabolic activity. Fresh, washed and sonicated samples exhibited similar results. Grinding only affected TiO_2 (increase) and ZnO (decrease).
Reference: Kendall et al. (2004, 156634) **Species:** Human **Tissue Type:** BALF (obtained by bronchoscope from 6 nonsmokers and 3 smokers)	$PM_{2.5}$ sample sites; 2 schools in Bronx, NY, 6 background urban, 6 urban roadside. Sampling occurred 24 h/day for 12 days. Particle Surface Chemistry: 79-87% carbonaceous material (Ch, COO, C-(O,N)), 10-17% O (O1s), 1.5-4% N (NH_4^+, N-C, NO_3^{2-}), 0.6-1% S, and 0.3-2 % Si. Only NO_3 - higher in roadside samples. NH_4 and NO_3 - correlated with NO and NO_X in air but not NO_2. **Particle Size:** $PM_{2.5}$	**Route:** BALF interaction **Dose/Concentration:** 5-10 ml of 0.5 M NaCl or BALF **Time to Analysis:** Filters treated with BALF for 4 h	**Saline Washing:** Removed particles and decreased NH_4, NO_3, O and S relative to C1. **BALF treatment (XPS):** $PM_{2.5}$ surfaces interacted strongly with BALF within hours of contact. Specific surface components of $PM_{2.5}$ immersed in BALF were desorbed while biomolecules from BALF were adsorbed to particles. N-C on the PM surface increased 3 fold for smokers and 4 fold for nonsmokers (range 1.4-7.4). This is most likely related to protein-like adsorption on PM. Treatment also induced a slight increase in COO and decreases in NH_4, NO_3, O and S. **ToF-SIMS - Organics:** Particle loading and surface hydrocarbons showed a linear correlation. Loss of hydrocarbons from $PM_{2.5}$ surface averaged 55% (10-75) after undergoing saline and BALF washes. In only 3/12 samples BALF removed less hydrocarbon. BALF treatment increased the amino acid and phospholipid content of the $PM_{2.5}$ surface. **ToF-SIMS - Inorganic:** Saline washing appeared to increase Al and Si but with extreme variability; this increase was not statistically significant. Both saline and BALF washing decreased NH_4 and Na levels to a similar extent. BALF washing did not affect Al or Si.
Reference: Kim et al. (2005, 088454) **Species:** Human **Cell Type/Line:** BEAS-2B	Zn^{2+} **Particle Size:** NA	**Route:** Cell Culture **Dose/Concentration:** 15, 50, 100 µmol **Time to Analysis:** 1-20 h	**Cell Viability:** At 50 µM for 20 h, no apoptosis was induced. **IL-8:** At 12 h, IL-8 increased in dose-dependent manner. At 15 or 50 µM, Zn^{2+} increased protein 1.6 and 4.6 fold respectively. IL-8 mRNA expression increased dose-dependently, reaching statistical significance at 2 h and continuing until 4 h. **EGFP (adenoviral IL-8 promoter):** Levels increased 2.4 fold with 50 µM Zn^{2+}. **Proteases:** With 50 µM Zn^{2+}, phosphorylation of MAPKs ERK, JNK and p38 increased by 15 min and continued increasing up to 2 h. Pre-exposure of inhibitors of MEK, JNK, before Zn^{2+} exposure caused inhibition of Zn-induced IL-8 mRNA and protein production. Inhibitor of p38 had no effect. Dephosphorylation of ERK and JNK was partially inhibited with exposure to Zn^{2+}.

Study	Pollutant	Exposure	Effects
Reference: Kleinman et al. (2003, 087938) **Species:** Rat **Strain:** Wistar Kyoto, F344 **Age:** 22-24 mo, 10 wk **Cell Type/Line:** AM	UF1: Utrecht 1 Fine (urban freeway) UC1: Utrecht 1 Coarse UF2: Utrecht 2 Fine (urban, freeway, light industrial) UC2: Utrecht 2 Coarse SRM 1650 SRM 1648 **Particle Size:** UF1: 0.2-2.5 µm; UC1: 2.5-10 µm; UF2: 0.2-2.5 µm; UC2: 2.5-10 µm	**Route:** Cell Culture (10^5 cells/well at 10^6 cells/mL) **Dose/Concentration:** 1.2 to 1200 ng/10^6 cells **Time to Analysis:** 4, 18 h	**Macrophage PMA-stimulated respiratory burst activity:** SRM 1648 and 1650 induced dose-dependent decreases approaching 0 at 50 -100 µg/10^5 cells. Large dose-dependent decreases from old rat AMs exposed to fine PM exposure were followed by young rat AMs exposed to fine PM. However, no age-related effects were statistically significant. **Free radical production:** All coarse particles depressed free radical production in a semi-dose-dependent manner, with UC2 exhibiting more potency than UC1. Both fine particles also showed dose-dependent responses but UF1 and UF2 responses were greater than the control at 3 µg/10^6 cells. **PM Characterization:** Ratios between coarse and fine PM were similar for metals tested (Al, Fe, Mn, Zn). Al was higher in coarse samples and Zn higher in fine PM, although large variability was observed. Fe and Mn results were roughly equivalent for all samples.
Reference: Kocbach et al. (2008, 198874) **Species:** Human **Cell Type/Line:** THP-1	PMW: Wood smoke particles Collected from conventional Norwegian wood stove burning birch PMT+: Traffic-derived particles; collected from road tunnel in winter when studded tires were used PMT-: Traffic-derived particles; collected from road tunnel in summer without studded tires DEP: SRM2975 Porphyr: fine grain syenite porphyry (prepared by SINTEF, Trondheim, Norway) Polymyxin B Sulphate (endotoxin inhibitor) **Particle Size:** PMW, PMT, DEP: NR; Porphyr 8 µm (mean)	**Route:** Cell Culture (1×10^6 cells/mL) **Dose/Concentration:** 30-280 µg/mL **Time to Analysis:** 2, 5, 12 h	**Particle Characterization:** PMT+ contained a high mineral particle content. PMT- contained carbon aggregates, and polycyclic aromatic hydrocarbons (PAH). PMW and DEP contained carbon aggregates. PAH content of PMW was greater than DEP. Porphyr was not included in the analysis. **Cytokines:** PMT± induced releases of TNF-α, IL-1β, and IL-8 with 30 or 70 µg/mL. PMW similarly induced TNF-α and IL-8. DEP induced IL-1β and IL-8. Porphyr induced IL-8 increases. IL-4, IL-6 and IL-10 were unaffected. Overall, the order of effective cytokine induction from most to least effective was PMT±, PMW, DEP, and Porphyr. mRNA expression of TNF-α, IL-1β, IL-8, and IL-10 increased with 140 µg/mL of PMT± and slightly for PMW. **LDH:** PMT ± induced small but statistically significant increases at low doses. DEP increased LDH at 280 µg/mL only. **Polymyxin B Sulphate:** The endotoxin inhibitor significantly inhibited LPS-induced cytokine release by 80-90% and reduced PMT± induction by 50-60%. **Organic Extraction:** PMT+ washed and native particles showed equivocal induction of cytokine release. PMT+ organic extract had no effect. PMT- and PMW organic extracts significantly increased TNF-α and IL-8. Washed particles induced less significant increases of IL-8. DEP organic extract had no effect.

Study	Pollutant	Exposure	Effects

CFE = 80% C, 2% Fe, 2% Si, 16% O. CFE+ = 20% C, 6% Al, 3% Si, 50% F, 6% O, 11% N, 4% Na. CFA = 25% C, 3% Fe, 13% Al, 17% Si, 41% O, 1 % N. DEP = 70% C, 3% Fe, 24% O, 1% N, 2% S. **Particle Size:** CP, CFE, CFE+: approximately 1 µm (resembling zeolite); CFA: <2 µm; DEP: 150 nm	**Route:** Cell Culture (4×10^6 cells/well) **Dose/Concentration:** CP: 5-50 µg/cm^2; CFE: 2.5-25 µg/cm^2; CFE+: 2.5-25 µg/cm^2; CFA: 10-100 µg/cm^2; DEP: 2.5-25 µg/cm^2 **Time to Analysis:** 4, 8, or 24 h	**Cytotoxicity:** CP exhibited no effects. DEP and CFE exhibited intermediate toxicities in the range of 50-70 µg/cm^2. No toxicity was apparent when treated with CFA (up to 200 µg/ cm^2) or synthesized C particulates. **Endothelial Activation:** ICAM-1, VCAM-1, and E-selectin were activated dose-dependently by DEP, CFE, and CFE+. No effects observed for CFA or CP. These effects were not the result of endotoxin release. **Individual Variability:** Donors (humans) showed variability in responses especially for CFA. 3/9 had a medium response negated by ND responses in 6/9.
Reference: Kubatova et al. (2006, 198835) **Species:** Rat, Human **Cell Type/Line:** RAW 264.7, BEAS-2B	PMW: Wood Smoke Collected from airtight wood stove burning hardwoods -P: Polar (fraction extracted from 25-50 C) -MP: Mid Polar (fraction extracted from 100-150 C) -NP: Nonpolar (fraction extracted from 200-300 C) -C: P + MP + NP **Particle Size:** NR	**Route:** Cell Culture (RAW 264.7: 10^6 cells/mL; BEAS-2B: 10^5 cells/mL) **Dose/Concentration:** 50, 100, 200 µg/mL **Time to Analysis:** 12 h	**GSH:** PMW-MP and PMW-NP induced GSH depletion substantially in a dose dependent manner starting at 50 µg/mL in both cell types. DMSO had no effect. **Cytotoxicity:** PMW-MP and PMW-NP increased cytotoxicity at 200 µg/mL in RAW 264.7. BEAS-2B was unaffected. **Particle Characterization:** PMW-MP contained higher concentrations of oxy-PAHs, disyringyls, syringylguaiacyls and PAHs. oxy-PAHs include 9-fluorenone, 1-phenalenone, 9,10-anthraquinone and hydroxycadalene. PAHs included phenanthrene, fluoranthene and pyrene. **Effects of Individual Components of PMW-MP on GSH:** 1,8-dihydroxy-9-10anthraquinone and 9,10-phenanthraquinone depleted GSH. 9,10-anthraquione, anthrone, 1-hydroxypyrene increased GSH. Phenanthrene, 1-methylpyrene, 9-fluorenone and xanthone had no effect.
Reference: Kubatova et al. (2004, 087986) **Species:** Monkey **Cell Type/Line:** African green monkey kidney cells designated COS-1 (CV-1 cells with origin - defective mutants of SV40), E coli PQ 37 (SOS Chromotest)	DEP: Obtained from diesel bus PMW: Wood smoke particulates obtained from airtight wood stove burning hardwood HSF: Hot pressure fractionation -C: P + MP + NP -P: Polar -MP: Mid Polar -NP: Nonpolar OE: Organic Extraction -HNP: n-hexane nonpolar -MEP: methanol polar **Particle Size:** NR	**Route:** Cell Culture (10,000 cells/180 µl) **Dose/Concentration:** 0, 50, 100, 150, 200, 250, 300 µg/mL **Time to Analysis:** Cytotoxicity: 24 h; Chomotest: 2 h SOS	**Cytotoxicity:** PMW induced cytotoxicity in a dose-dependent manner. PMW-HNP induced low cytotoxicity, followed by PMW-C (intermediate) and PMW-MEP (highest). Levels above 25 µg/mL were cytotoxic. DEP-HNP induced cytotoxicity but was not dose-dependent. Results similar for all 3 fractions (highly variable). All fractions with concentrations higher than 100 µg/mL were cytotoxic. **Extraction Water Temperature Effect:** PMW was cytotoxic at temperatures over 50 C. DEP was cytotoxic at temperatures higher than 200˚ C. At 250˚, cytotoxicity between DEP and PMW was similar. At 300˚ C, PMW cytotoxicity declined and DEP stayed high, resulting in DEP inducing higher cytotoxicity than PMW. **SOS Chromotest:** β-Galactosidase formation increased, peaked at 200˚ C with DEP and declined to control at 300˚ C. Individual fractions showed linear dose response from 25-200 µg/mL with 150˚ C and 200˚ C extracts significantly higher.

Study	Pollutant	Exposure	Effects
Reference: Lee et al. (2005, 156682) **Species:** Human **Cell Type/Line:** A549	MEP: Motorcycle Exhaust Particles (Yamaha Cabin engine, 95 octane unleaded gasoline,150 rpm) MEPE: MEP Particle Free **Particle Size:** MEP 0.5 µm; MEPE<0.2 µm	**Route:** Cell Culture (1×10^5 cells/well) **Dose/Concentration:** MEP 0.02, 0.2, 0.2, 2, 20 µg/mL; MEPE 20 µg/mL **Time to Analysis:** 24 h	**IL-8:** MEP induced IL-8 at concentrations greater than 0.2 µg/mL. Levels increased 2fold at 24 h with 20 µg/mL. MEPE induced similar responses at 20 µg/mL. Induction of IL-8 mRNA expression was dose-dependent with MEP and MEPE. **Cytotoxicity:** Exposure to particles did not affect cytotoxicity. **NF-κB:** MEP (20 µg/l) induced time-dependent activation for 2 h and continued at same level for up to 6 h. Pretreatment of PDTC (1mM) fully inhibited MEP induction. **MAP Kinase:** MEP induced time-dependent activation up to 30 min and stayed elevated for at least 60 min. **ROI:** MEP treatment induced a time-dependent increase in ROI for up to 1 h and then continued the at same level for up to 6 h.
Reference: Lee and Kang (2002, 198864) **Species:** Mouse **Cell Type/Line:** Peritnoeal Macrophages, RAW 264.7	MEP Yamaha 2-stroke engine using unleaded gas) MEPE(particle-free MEP) **Particle Size:** 0.5 µm	**Route:** Cell Culture (5×10^5 cells/mL (Cytotoxicity), 3×10^5 cells/mL (Apoptosis), 2×10^6 cells (MMP and ROI), 1×10^7 cells (GSH) **Dose/Concentration:** 5, 10, 50, 100, 300, 1000 µg/mL **Time to Analysis:** 6, 12, 18, 24 h	**Cytotoxicity:** Viability decreased dose and time-dependently in all cell types at 24 h. **Apoptosis:** subG1 significantly and dose-dependently increased at the 300 MEP µg/mL dose in all cell types, indicating increased apoptosis. MEPE induced similar results. Inhibition was successful against MEP-induced apoptosis by calcium chelators EGTA, BAPTA-AM, cyclosporin A and antioxidants NAC, GSH, catalase and SOD. **Ca2+**: MEP and MEPE increased Ca^{2+} at 300 µg/mL. BAPTA-AM completely inhibited induction. **ROI:** MEP increased ROI in a time-dependent manner. Calcium chelators and antioxidants substantially attenuated induction. **GSH:** MEP significantly decreased GSH. **MMP:** Mitochondria membrane potential decreased dose-dependently with MEP 100 µg/mL and 300 µg/mL. Calcium chelators and antioxidants partially inhibited reduction.

(2002, 042080) **Species:** Mouse **Cell Line:** RAW 264.7, THP-1	VACES (Biosampler PM_{10} in Downey, CA -DEP concentrate in water) DEPM (DEP methanol extract) DEPME (DEP methylene chloride extracts) DEPAL (DEPME aliphatic (hexane)) DEPAR (DEPME aromatic (hexane/methlene chloride)) DEPPO (DEPME polar (methylene chloride/methanol)) **Particle Size:** NR	**Route:** Cell Culture (2×10^6 cells/well Mouse RAW 264.7 and THP-1; 0.67×10^6 cells/well Murine RAW 264.7) **Dose/Concentration:** 10-200 µg/mL JNK Activation and IL-8 Production: THP-1 cells- 0, 10, 25, 50, 100 µg/mL DEPM; THP-1 cells- 0, 10, 25, 50, 100 µg/mL of DEP; RAW264.7 cells- 10 -100 DEP µg/mL Cytotoxicity: 1, 10, 25 (THP-1 cells only), 50, 100, 200 µg/mL GHS/GSSG: 0, 10, 25, 50, 100 µg/mL HO-1 Expression: 0, 25, 50, 100, 200 µg/mL **Time to Analysis:** GHS/GSSG: DEPM, whole DEP (RAW 264.7 only) 8 h. HO-1, MnSOD Expression: RAW 264.7, THP-1 7h. RAW 264.7 cells exposed to whole DEP 16 h. JNK Activation, IL-8 Production: THP-1 cells 30 min, 16 h. RAW 264.7 cells 90 min. Cytotoxicity: RAW264.7, THP-1 18 h.	**GSH/GSSG Ratio:** DEPM induced dose-dependent decrease in GSH/GSSG ratios in both cell lines. DEP induced decreases at comparable doses to DEPM. **HO-1 Expression:** Cells exhibited dose-dependent increases in HO-1 expression. **HO-1 Expression in Murine RAW 264.7:** VACES-F consistently induced HO-1 expression over a 9m period, whereas VACES-C was effective in inducing HO-1 during fall and winter. HO-1 induction positively correlated to higher OC and PAHs that were represented in VACES-F, but also seen with a rise in PAHs in VACES-C during winter months. **MnSOD:** At doses of 2.5 µg/mL, DEPM increased MnSOD in THP-1 cells. **JNK Activation:** DEPM dose-dependently increased JNK phosphorylation but did so without a change in the JNK expression level. DEP-exposed mouse RAW264.7 cells exhibited similar increases in JNK phosphorylation but without increasing JNK expression. **IL-8:** Exposure to DEPM elicited dose-dependent increase in IL-8 levels of THP-1 cells.

Study	Pollutant	Exposure	Effects
Reference: Li et al. (2002, 087451) **Species:** Human **Cell Line:** BEAS-2B, NHBE, THP-1 macrophages	DEPM (DEP methanol extract) DEPME (DEP methylene chloride extracts) DEPAL (DEPME aliphatic (hexane)) DEPAR (DEPME aromatic (hexane/methlene chloride)) DEPPO (DEPME polar (methylene chloride/methanol)) **Particle Size:** 0.05-1 µm	**Route:** Cell Culture (10^6 cells/mL) **Dose/Concentration:** 0, 10, 25, 50, 100 µg/mL **Time to Analysis:** 30, 60, 120 min	**ROS:** BEAS-2B cells demonstrated increased HE fluorescence, indicating increased ROS formation. THP-1 cells were unaffected. **GSH/GSSG Ratio:** DEPM dose-dependently decreased GSH/GSSG in THP-1 and BEAS-2B cells. Similar changes occurred with NHBE cells. THP-1 cells maintained a higher ratio of GSH/GSSG than BEAS-2B and NHBE cells. **NAC on GSH/GSSG Ratio:** Exposure to DEPM in the presence of NAC did not affect the GSH/GSSG ratio in BEAS-2B and NHBE cells. In THP-1 cells, NAC prevented a decline in the GSH/GSSG ratio. **MnSOD and HO-1:** THP-1, BEAS-2B and NHBE cells showed constitutive MnSOD expression and dose-dependent expression of HO-1 protein and mRNA. No change occurred in the expression of β-actin. **DEPAL, DEPAR, DEPPO, CoPP on HO-1 Expression:** DEPPO was more potent than DEPAR. DEPAL lacked activity for THP-1 and BEAS-2B cells. The potency of DEPPO was sufficient to affect cellular viability and HO-1. CoPP induction of HO-1 failed in THP-1 cells, but succeeded in BEAS-2B cells. However, it did not protect against the oxidizing effects of DEPM. **JNK:** JNK activation increased in DEP-exposed THP-1 and BEAS-2B cells. JNK isoforms were observed at doses of ≥ 25 µg/mL. In BEAS-2B cells a high rate of cell death diminished this response at 100 µg/mL. NHBE also showed increased JNK phosphorylation at doses 50 - 100 µg/mL. **NAC on JNK:** NAC led to inhibition of JNK activation. **IL-8:** THP-1 cells showed dose-dependent increases of IL-8. NHBE cells showed incremental increases followed by rapid decline at 100 µg/mL attributed to apoptosis. BEAS-2B cells responded to 10 µg/mL with increased IL-8, but cellular toxicity and cell death led to a drop in IL-8 production at higher doses. **Cytotoxicity:** Comparing cytotoxicity at 25 µg/mL DEP, BEAS-2B cells had a higher rate of cell death than THP-1 cells. BEAS-2B cells showed a significant rise in cell death at doses larger than 10 µg/mL. In THP-1 cells, it took doses of 25 µg/mL or more before significant increases occurred. In BEAS-2B, cell death began at 2 h. In THP-1, increases in cell death prolonged for 8h or longer. NHBE cells also showed increase rates of cytotoxicity compared to macrophages. NAC in THP-1 interfered with a generation of cytotoxicity, but NAC did not have any decreasing effect on cell death in BEAS-2B or NHBE cells.

Study	Pollutant	Exposure	Effects
Reference: Lindbom et al. (2007, 155934) **Species:** Mouse **Cell Line/Type:** RAW 264.7	PM_{10}: -ST: Street -S: Subway -G: Granite -Q: Quartzite (-G and -Q generated by road simulator at Swedish National Road and Transport Research Institute) **Particle Size:** PM_{10}: Bimodal with peaks around 4-5 um and 7-8 um.	**Route:** Cell Culture (130,000 cells/cm^2) **Dose/Concentration:** 1, 10 or 100 µg/mL **Time to Analysis:** 18, 24 h Analysis of Arachidonic Release (AA): Cells pre-incubated w/ 1 µCI tritium marked for AA and washed exposed to 10, 50, 100 and 250 µg/mL	**Cellular Viability:** Viability was not influenced by any particle types and in all cases exhibited 90% or higher viability, except for the combination of subway particles and NAC where viability dropped to 20%. **Cytokines:** All particles induced TNF-α secretion in a dose-dependent fashion. PM-S was most potent at 1 µg/mL. PM-G and PM-ST induced effects at 10 µg/mL. PM-Q induced increase of TNF-α at 100 µg/mL.PM-ST induced IL-6 release at 10 µg/mL. PM-G, PM-Q, PM-S induced IL-6 secretion at 100 µg/mL. DFX inhibited TNF-α in cells exposed to PM-S and PM-ST. DFX induced increase of TNF-α with PM-Q. For all PM types (except PM-ST) DFX inhibited induced IL-6 secretion. **NO:** PM-ST and PM-G induced a significant release of NO, with PM-ST inducing a higher NO release than PM-G. **NAC:** NAC treatment significantly inhibited both TNF-α and IL-6 secretion with all PM particles. **L-NAME**: L-NAME caused a decrease in NO secretion at 100 µg/mL of PM-ST. L-NAME did not have an effect on granite-induced NO secretion at 100 µg/mL. **Cytokine Gene Expression:** TNF-α mRNA showed a trend to increase for -ST, but this did not reach significance. IL-6 gene expression increased for PM-Q, PM-ST, PM-S but not for PM-Q. **AA Release:** PM-S exposure at 100 and 250 µg/mL was the only PM to induce AA release. **Lipid Peroxidation:** All particle types induced lipid peroxidation. PM-S and PM-ST induced significantly higher lipid peroxidation as compared to PM-Q and PM-G. **ROS:** All particle types induced ROS formation. PM-S and PM-ST induced significantly higher formation at 10 µg/mL. PM-Q and PM-G induced small but significant decreases in absorption at 100µg/mL. Both PM-ST and PM-S had significant dose responses for all concentrations tested. No difference was observed between PM-G and PM-Q. PM-S and PM-ST pretreated with DFX had a lower ability to induce ROS formation. **Endotoxin Content:** Only PM-ST showed positive results for endotoxin content.

Study	Pollutant	Exposure	Effects
Reference: Liu et al. (2005, 088304) **Species:** Human **Cell Type:** HPAECs	SE: Wood Smoke Extract; generated using a stainless steel receptacle containing 100g of dry wood dust **Particle Size:** NA	**Route:** Cell Culture **Dose/Concentration:** 40 µg/mL **Time to Analysis:** 0-4 h; Mitochondrial Membrane Destabilization: 0-60 min; DNA Defragmentation: 0-6 h; Cytotoxicity: 24 h	**Viability:** SE exposure reduced cell viability dose-dependently. Reduction reached ~38% of control. **Effect on Oxidative Stress/ Antioxidant Enzymes:** SE caused an increase in ROS levels, in particular O_2- and $H2O_2$ in a time-dependent manner. Exposure to SE for up to 4 h caused a decrease in GSH levels in a time-dependent manner. Increased expression of Cu/Zn SOD mRNA and HO-1 mRNA was observed. Catalase or GPx mRNA expression was unaffected. Upregulation of Cu/Zn SOD and HO-1 occurred in a time-dependent manner **Mitochondrial Translocation/ Capsase-Independent Apoptosis/DNA fragmentation:** Exposure for up to 60 min caused an increase in the percentage of annexin V-FITC-pos cells but not PI-pos cells. At 4 h, FDA-pos cells was unaffected. SE exposure caused a loss of mitochondrial membrane potential (indicated by the change in JC-1 fluorescence). Cytosolic bax levels increased after exposure for 1 or 2 h and returned to basal level at 4 h after exposure. Levels of procaspase-3 and caspase-9 were unaltered by SE exposure after 4 h. Procaspase-3 increased and caspase-9 decreased by $H2O_2$ exposure. SE exposure increased levels of AIF and EndoG (exposure up to 4 h). At 6 h, increased DNA defragmentation was observed. Pre-treatment with caspase inhibitors (CMK and Z-VAD-FMK) failed to suppress SE-induced apoptosis. **NAC:** Treatment with NAC prevented ROS increase in cells exposed to SE for 60 min. NAC addition prevented the reduction of GSH by SE. NAC decreased nuclear levels of AIF and EndoG and completely reduced DNA-fragmentation. NAC alleviated the SE-induced reduced viability. GSH and DNA fragmentation were unaffected by NAC.
Reference: Long et al. (2005, 087454) **Species:** Human **Cell Types:** Human, Peripheral blood mononuclear cells (PBMCs) differentiated into MDMs (90-95 % CD14+) and T lymphocytes	Synthetic C and C/Fe particles (phenol and paraformaldehyde polymers on a zeolite template) C/Fe analysis Al 1.38 %, Si 0.33 %, Fe 0.46% **Particle Size:** 1 µm	**Route:** Cell Culture (5×10^6 cells, 2 mL /well MDMs) **Dose/Concentration:** 5 µg/cm^2 **Time to Analysis:** 2-24 h	**ROS release:** Oxidative burst form C/Fe maxes out at 20 min with no effect from C particles. **Cellular particulate actions:** C particulates were present within lysosomes with small clumps forming after 24 h outside of lysosomes with no evidence of organelle lysis and/or agglomeration. C/Fe particulates showed similar initial effects progressing at 24-h total organelle lysis extending to the outer cell membrane. **T cell effects:** No effects from C or C/Fe particles Medium Effect: Particle agglomeration appears to be a direct result of serum present within a cell free medium **Hydroxyl radical formation:** C/Fe particles showed an order of magnitude of higher hydroxyl formation as compared to C particles

Study	Pollutant	Exposure	Effects
Reference: Ma et al. (2004, 088417) **Species:** Mouse **Cell Line:** JB6P+ (Epidermal Cell Line)	DEP: SRM 1975 **Particle Size:** 0.5 µm	**Route:** Cell Culture **Dose/Concentration:** Non-cytotoxic: 5, 10, 20 µg/mL; Cytotoxic: 0, 10, 20, 40, 80, 100, 160 µg/mL **Time to Analysis:** 24, 48 h; NF-κB and AP-1: 12 h Phosphorylation of Akt: 5- 120 min. Effect of LY294002 on DEP: Cells pretreated with LY294002 (0 or 10 µM) for 30 min and then exposed to DEP for 0-60 min.	**Viability:** Below 20 µg/mL, DEP had no effect. At concentrations greater than 20 µg/mL, DEP caused apoptosis. **NF-κB and AP-1:** DEP stimulated NF-κB activity at 5 and 10 µg/mL. At 20 µg/mL, NF-κB activity decreased, but was still greater than the control. DEP had no effect on AP-1 activity. **PI3K/Akt Signaling Pathway:** DEP induced phosphorylation of Akt on both Thr-308 and Ser-473. LY294002 (an inhibitor of P13K) blocked phosphorylation of Akt, p70/p85 s6 kinase and GSK 3b. LY294002 eliminated DEP-mediated phosphorylation of Akt. Inhibition of P13K by expressing p85 also blocked DEP-induced Akt phosphorylation. DEP induced phosphorylation on GSH-3B on Ser-9 without affecting tyrosine phosphorylation and enhanced phosphorylation of p70/p85 S6 kinase on Thr-389. DEP had no effect on phosphorylation of FKHR. **SAPK/JNK Pathway:** DEP slightly activated the pathway. Increased transient activation of MKK4 (a signal component of the SAPK/JNK pathway) and thus enhanced phosphorylation of SAPK/JNK. DEP promoted phosphorylation of c-Jun and ATF-2. DEP did not affect p38 MAPK or ERK phosphorylation. **LY294002:** Treatment with LY294002 (P13K inhibitor) eliminated DEP-induced NF-κB activity. A similar effect was observed with the use of another P13K inhibitor, wortmannin. TDZD-8 (GSK-3B inhibitor), D-JNKI(a JNK inhibitor), SB202190 (inhibitor for p38 MAPK) or PD98059 (inhibitor for MEK1) had little effect on DEP-mediated NF-κB activation.
Reference: Maciejczyk and Chen (2005, 087456) **Species:** Human **Cell Type:** BEAS-2B	CAPs: $PM_{2.5}$ Collected via cyclone inlet on side of building in Tuxedo, NY. Weekdays 9-3 March 4 to September 5, 2003 Mass contributions of the Regional Sulfate, Soil, Oil- Combustions and Unknown/other categories to CAPs are: Regional Sulfate- 65%, Soil- 20%, Unknown/Other- 13% and Oil Combustion- 2%. Composition: * Regional Sulfate characterized by high concentrations of S, Si and . * Soil characterized by high concentrations of Ca, Fe, Al and Si. * Oil-Combustion characterized by high concentrations of V, Ni and Se. **Particle Size:** $PM_{2.5}$	**Route:** Cell Exposure (subchronic exposures); Cell Culture (NF-κB) (9×10^4 cells/well) **Dose/Concentration:** CAPS 109 ± 178 $\mu g/m^3$ (air exposure); 300 µg PM/ml (culture) **Time to Analysis:** 24 h	**NF-κB:** NF-κB response most notably correlated with V and Ni - elements associated with oil combustion source category (oil combustion makes up the group that is the smallest percentage of CAP mass).

Reference: Madden et al. (2003, 198877) **Species**: Human **Cell Type:** NHBE	DEP(SRM 2975) Diesel Exhaust Extracts from a High load (HL~75% engine load) or Low load (LL 0% engine load): Obtained from Caterpillar diesel engine, 4 cycl, 4 stroke, model 3304 Particle Characterization: LL extract has greater amount of low-molecular-weight carbonyls (2-5 carbons). HL had more intermediate size carbonyls (6-9 carbons). Largest carbonyls analyzed (11-12 carbons) found in similar ratios in the two types of extract (number of carbons is indicative of differences in boiling points). **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 0, 10, 50, 100, 250, 500 µg/well **Time to Analysis:** 24 h (after 2 h of treatment, 0.5 ml of BEGM added to each well and cells incubated for an additional 22 h) .	**Cytotoxicity:** LL, HL and SRM had no effect on LDH release. **51Cr:** Incubation of cells with LL or SRM (10 to 500 µg/well) had no effect. 500 µg/well of HL induced a significant increase in 51Cr release. **IL-8:** HL induced a 5-fold increase in IL-8 at 500 µg/well. A decrease was observed at the highest dose of LL extract. SRM did not significantly alter IL-8 production. **PGE2:** Production of PGE2 (inflammatory/immune mediator) increased in cells treated with HL extract at 500 µg/well. LL had no effect. Stimulation with melittin caused LL extract to have inhibitory effect on PGE2 at 500 µg/well. SRM had no effect.
Reference: Matsuo et al. (2003, 198879) **Species:** Human **Cell Type:** NHBE, NHPAE, TIG-1, TIG-7 (normal human lung embryonic fibroblasts)	DEP: prepared at National Institute for Environmental Studies (Tsukuba, Japan) RDEP: residual DEP (after sequential extraction with hexane (NOS), benzene, dichloromethane, methanol, 1N ammonium hydroxide) **Particle Size:** 0.4 µm (MMAD)	**Route:** Cell Culture (NHBE: 5×10^4 cells/cm^2; NHPAE: 3×10^3 cells/cm^2; TIG-1 and TIG -7: 3×10^3 cells/cm^2; Apoptosis: 2×10^5 cells/cm^2; ROS/NO: 2×10^4 cells/cm^2; Cytotoxicity Modulating Agent: 3×10^4 cells/cm^2; GSH: 3×10^4 cells/cm^2) **Dose/Concentration:** 25, 50, 100, 200, 300, 400, 500 µg/mL **Time to Analysis:** 1 h	**Cytotoxicity in NHBE:** Both DEP and RDEP exhibited dose-dependent cytotoxicity at concentrations beginning from 50 µg/mL and higher. RDEP was less cytotoxic than DEP. DEP exposure resulted in necrosis, not apoptosis. **Comparative Cytotoxicity:** The order of LC50 values (50% lethal concentration) was: NHBE (118 µg/ml), NHPAE (137 µg/ml), TIG (270 µg/ml). NHBE's susceptibility was higher than the susceptibility of NHPAE and TIG cells. **ROS/NO:** DEP induced dose-dependent increases at 25 and 50 µg/mL. **Reduced Glutathione:** DEP induced dose-dependent decreases. At 200 or 300 µg/mL, GSH levels decreased by 55.2 or 97.3%, respectively. **Antioxidant Effects:** Various antioxidants either decreased DEP cytotoxicity (PMC, Ebselen, EUK-8) or had no effect on DEP cytotoxicity (SOD, catalase, GSH, α-tocopherol) **Chelating Agents:** DEP became less cytotoxic when Ion-chelating agents were preincubated for 24 h. No effect on DEP cytotoxicity was observed when chelating agents were administered to cells immediately after sonication. **Endocytosis inhibitors:** Decreased DEP toxicity was observed in a dose-dependent manner.
Reference: Matsuzaki et al. A significant increase was observed (243%) at 24 h with 30 µg/mL. **LTB-4:** At 2 h, LTB4 increased to 115% and 119% with 30 and 60 µg/mL me-DEP respectively. At 24 h with 60 µg/mL me-DEP, LTB-4 increased to153%. **H_2O_2:** Exposure to 30 and 60 µg/mL of me-DEP induced large dose-dependent increases of 563% and 1220%, respectively. **MMP-9:** A significant increase at 2 and 24 h were observed. In both exposure periods, 30 µg/mL induced larger increases than 60 µg/mL.

Study	Pollutant	Exposure	Effects
Reference: Molinelli et al. (2006, 198949) **Species:** Human **Cell Type:** NHBE, BEAS-2B	PMH: PM_{10} extracts in hexane PMA = PM_{10} extracts in acetone of residue after hexane extraction -G: Guaynabo(Urban) and -F: Fajardo (Preservation Area) **Particle Size:** PM_{10}	**Route:** Cell Culture (3×10^3 cells/well) **Dose/Concentration:** NHBE exposed to 0-100 µg/mL of PM_{10} BEAS-2B exposed to 10,100, 250 µg/mL of PM_{10} **Time to Analysis:** 48 h	**Metal analysis:** Hexane extracts Cu, V, Ni all higher in winter than summer. For hexane extracts within the same season, metal concentrations were higher in the Fajardo extracts. On the other hand, the acetone extracts from Guaynabo generally had higher metal concentrations than Fajardo. **Cytotoxicity NHBE:** The order of most to least toxic for PM extracted with hexane is: winter-G, winter-F, summer -G , summer-F. The order of most to least toxic for PM extracted with acetone is: summer-G, summer-F, winter-g. **Cytotoxicity BEAS-2:** For PM extracted with hexane, the cytotoxicity order is: winter-G, winter-F, summer-G, summer-F. The order for acetone extracted PM is: summer-G , summer-F, winter-F, winter-G. Effects trend similar to metal levels (no analysis). Summer extracts showed linear dose-response curves. Winter extracts exhibited more equivocal results, especially for Fajardo. Results suggest that NHBE cells are more sensitive than the BEAS-2B cells to PM extracts.

DEP and UrbD induced similar results. **Cytoskeleton of BD-AM:** $ufTiO_2$ and $fTiO_2$ both induced some retarded relaxation and increased stiffening at 100 µg/mL dose. $ufTiO_2$ appears to increase stiffening in a dose-dependent manner. ufEC90 induced dose-dependent acceleration of relaxation due to the carbon content of ufEC90. DEP also induced acceleration of relaxation as well as a decrease in stiffness. **Phagocytosis:** At 24 h, $ufTiO_2$ and $fTiO_2$ significantly reduced phagocytic ability in J774A.1 but not in BD-AM. All carbonaceous particles induced significant impairment in J774A.1. All ultrafine carbon particles inhibited BD-AMs. **Cell Proliferation:** $ufTiO_2$ significantly inhibited proliferation compared to the control and $fTiO_2$ at 100 µg/mL in J774A.1. ufEC90 and ufP90 inhibited proliferation slightly with ufEC90 inducing slightly greater inhibition than ufP90. UrbD and DEP also significantly reduced proliferating. **Apoptosis:** All particles induced decreased viability at 100 µg/mL in both cell types. With $ufTiO_2$ inducing greater apoptosis than $fTiO_2$, ufEC90 than ufP90 and ufEC90 than ufP-G.
Reference: Mutlu et al. (2006, 155994) **Species:** Human, Rat **Cell Type:** A549	PM_{10} (Collected by baghouse from ambient air in Dusseldorf, Germany) **Particle Size:** PM_{10}	**Route:** Cell Culture **Dose/Concentration:** 0.05, 0.5, 5. 50 $\mu g/cm^2$ **Time to Analysis:** 24 h	**Na, K-ATPase Plasma Membrane Protein:** PM_{10} induced a decrease of protein in the plasma membrane of A549 cells. Total Na,K-ATPase levels were unaffected. **ROS:** Pretreatment with EUK-134, superoxide dismutase and catalase mimetic, inhibited the decrease of GSH. Furthermore, it attenuated the decrease of NA,K-ATPase in A549 cells. **NA, K-ATPase Activity:** PM_{10} induced a dose-dependent decrease in ouabain-sensitive liberation of 32P from AT32P in primary rat alveolar type II cells. This effect was inhibited with pretreatment with EUK-134.

Study	Pollutant	Exposure	Effects
Reference: Nam et al. (2004, 198887) **Species:** Human **Cell Type:** A549	$PM_{2.5}$ Collected from hospital rooftop, Seoul, South Korea **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** 0.5, 1, 10, 25, 50 µg/cm^2 **Time to Analysis:** 6, 24 h	**NF-κB/IκBα:** 50 µg/cm^2 DEP induced IκBα degradation which peaked at 2 h and recovered after 4 h. Treatment with increasing amount of $PM_{2.5}$ resulted in a dose-dependent decrease in IκBα. $PM_{2.5}$ increased NF-κB in a dose-dependent manner up to 10 µg/cm^2. NF-κB induction peaked at 12 h. **IL-8:** $PM_{2.5}$ treatment increased protein level more than 3 fold with 100 µg/cm^2 $PM_{2.5}$. mRNA levels also increased. **iNOS Inhibitor:** $PM_{2.5}$ induced IL-8 elevation was completely blocked by iNOS inhibitor. iNOS inhibitor also negated $PM_{2.5}$ induction of NF-κB activity. Antioxidants and iNOS inhibitor reduced PM-induced IκBα degradation.
Reference: Nozaki et al. (2007, 097862) **Species:** Mouse **Cell Line:** LA-4 (Alveolar Epithelial Cells)	PM: Rooftop of 5 story building, urban, Japan PME: dichloromethane extract of PM filtered P90: Printex 90 (carbon black) (Degussa) **Particle Size:** PM: 0.22 µm; PME: 2.5 µm; P90: 14 nm	**Route:** Cell Culture (1.4×10^4 cells/cm^2) **Dose/Concentration:** 1.1 µg/cm^2 **Time to Analysis:** 24, 28, 72 h	**Cytotoxicity:** P90 had no effect. PM and PME were cytotoxic at similar levels. **Protein Expression:** All particles affected protein expression (no specific protein- 2D gel electrophoresis).
Reference: Obot et al. (2002, 042370) **Species:** Mouse **Cell Line:** BALB/c **Cell Type:** AM	PM: SRM 1648 PM-100: PM heated to 100° C PM-500: PM heated to 500° C PM-PH: PM acid digestion PMAC: Acetone extraction PMCH: Cyclohexane extraction PMH2O: Water extraction All extract fraction used as residual particles **Particle Size:** NR	**Route:** Cell Culture (5×10^5 cells/mL) **Dose/Concentration:** PM: 200 µg/mL; PM-100: 188 µg/mL; PM-500: 130 mg/l; PM-PH: 94 µg/mL; PMAC: 173 µg/mL; PMCH: 171 µg/mL; PMH2O: 188 µg/mL Fraction doses adjusted for mass loss during fraction treatment **Time to Analysis:** 4 h	**Cytotoxicity:** All 7 fractions had cytotoxic effects. PM had highest cytotoxicity. PM-500, PM-PH, PMAC less toxic than PM. **Apoptosis:** All 7 fractions significantly increased apoptosis. The PM fractions that induced the greatest apoptosis in descending order are: PM, PMH2O, PM-100, PM-500, PMAC, PMCH and PM-PH. PM-induced apoptosis (only PM, PM-500 and PMAC tested) was blocked by poly I or 2F8 antibody (scavenger receptors). **Particle Characterization:** Untreated PM and PM-100 did not have measurable amounts of transition metals on its surface. Measured components include carbon, O_2, N, S, Si, Ca, Al, P, Cl. PM-PH mostly contained O_2 and Si. PM-500 had increased O_2, Si compared to PM and measurable amounts of Na, K., Zn, Co, Pb, Fe. Included increased surface density of S, P, Al. PMCH lacked nonpolar organic compounds.
Reference: Obot et al. (2004, 095938) **Species:** Mouse (7-9wk), Human **Cell Line:** Mouse-BALB/c **Cell Type:** AM	PM: SRM 1648 (collected by bag-house in St. Louis, MO). PM-100: PM heated to 100˚ C PM-500: PM heated to 500˚ C PM-PH: PM acid digestion PMAC: Acetone extraction PMCH: Cyclohexane extraction PMH_2O: Water extraction All of the 6 extract fractions from PM1648 $PM_{2.5}$: Collected in Houston, TX **Particle Size:** PM1648: NR; $PM_{2.5}$	**Route:** Cell Culture (5×10^5 cells/mL) **Dose/Concentration:** PM: 200 µg/mL; PM-100: 188 µg/mL; PM-500: 130 mg/l; PM-PH: 94 µg/mL; PMAC: 173 µg/mL; PMCH: 171 µg/mL; PMH2O: 188 µg/mL Fraction doses adjusted for mass loss during fraction treatment $PM_{2.5}$ = 50, 100, 150, 200 µg/mL **Time to Analysis:** Mouse-4 h; Human-24 h.	**Human AM Viability:** Only PM, PM-100, PMAC and PMH2O decreased viability. **Human AM Apoptosis:** PM, PM-100 and PMH2O increased apoptosis. PM induced greater apoptosis than PM-100 and PMH2O. **Regression Analysis Mouse vs Human:** Although individual fractions differed somewhat, cell viability and apoptosis of all 7 fractions showed linear regression **Human and Mouse AM Viability with PM2.5:** Nearly identical dose-dependent decrease was exhibited starting at 50 µg/mL **Human and Mouse AM Apoptosis with $PM_{2.5}$:** Nearly identical dose-dependent increases were exhibited with human AM responses peaking at 150 µg /mL and declining at 200 µg/mL (no mouse data for 200 µg/mL). **Regression Analysis with PM2.5:** Excellent correlation of mouse and human responses for viability and apoptosis was exhibited.

Study	Pollutant	Exposure	Effects
Reference: Okeson et al. (2003, 042292) **Species:** Rat **Cell Type:** RLE-6TN (Type II Alveolar Epithelial Cells)	CG: Coal ash, Germany CU: Coal ash, USA 5C: PM # 5 Oil fly ash coarse 5F: PM #5 Oil fly ash fine 6MSC: PM #6 Oil med sulfur fly ash coarse 6HSC: PM # 6 Oil high sulfur fly ash coarse 6HSF: PM # 6 Oil high sulfur fly ash fine **Particle Size:** CG, CU: NR; 5C, 6MSC, 6HSC: >2.5 µm; 5F, 6HSF: <2.5 µm	**Route:** Cell Culture **Dose/Concentration:** Coal Fly Ash 12.5, 25, 50, 125, 250 µg/mL Oil Fly Ash - 100 µg/mL **Time to Analysis:** 24 h	**Oil PM Characterization:** Generally, the fine fractions had higher metal levels than the coarse fractions except for Zn. High sulfur had a higher metal content than med sulfur. Carbon percent weight was stable across all 5 fractions. **Coal Ash Cytotoxicity:** CG treatment exhibited similar cytotoxic results as CU. Cytotoxic effects were exhibited at concentrations of 12.5 µg/mL and above. Effects remained steady at concentrations above 50 µg/mL. **Oil Ash Cytotoxicity:** Cytotoxic effects were induced by all. The order of PM fractions inducing the most cytotoxicity to the least is the following: 5F, 6HSF, 6HSC, 5C, 6MSC. **Correlation of Metal Content and Cytotoxicity:** Fe, V showed a reasonable correlation. Zn had no correlation. **Cell Metabolism:** An inhibitory effect was observed with 100 µg/mL coal ash after 6 h. After 12 h of exposure, CU, unlike CG, does not continue to inhibit cell metabolism. Oil ash was generally less effective than coal ash. The order of PM fractions inhibiting metabolism the most to the least is the following: 5F, 6HSC, 5C, 6MSC. 6HSF not tested.
Reference: Okeson et al. (2004, 087961) **Species:** Rat **Cell Type:** RLE-6TN (Type II Alveolar Epithelial Cells)	Zn, V, Fe chloride as salts (valence state not reported) **Particle Size:** NR	**Route:** Cell Culture (50000 cells/well) **Dose/Concentration:** 0.001, 0.01, 0.1, 1.0, 10 mM **Time to Analysis:** 24 h	**Cytotoxicity:** All metals cytotoxic at concentrations greater than 0.1 mM. V is 5 times less cytotoxic than Zn, and Fe is 7 times less cytotoxic than Zn with a EC50 of 3mM and 4mM, respectively. At 10 mM of each metal, no surviving cells were present. **NCS:** Incubation with NCS (5 or 10 %) decreased toxicity of Zn, especially at 0.1 mM, but had no effect on Fe or V toxicity. **Albumin:** BSA decreased Zn toxicity at equivalent concentrations but to a lesser extent than NCS.
Reference: Osornio-Vargas et al. (2003, 052417) **Species:** Mouse **Cell Line/Type:** J774A.1, L929 (Mesenchymal Cells)	PM_{10} $PM_{2.5}$ -N = Northern (industrial) -SE = Southeastern (lake basin dust) sites, both heavy vehicular traffic, Mexico City, Mexico **Particle Size:** PM_{10}; $PM_{2.5}$	**Route:** Cell Culture (J774A.1: 15000 cells/cm^2; L929: 30,000 cells/well) **Dose/Concentration:** 20, 40, 80 µg/cm^2 **Time to Analysis:** 24-72 h	**PM Characterization:** Elements similar in particle types with elements in PM_{10} more abundant. Northern particles contained more Co, Zn, Ni, Pb. **Endotoxin:** All PM samples had detectable amounts of endotoxin. $PM_{2.5}$ -N had 22 EU/mg. PM_{10}-N had 30 EU/mg. $PM_{2.5}$ -SE had 12 EU/mg. PM_{10}-SE had 59 EU/mg. **Cytotoxicity (J774A.1):** The two northern samples, $PM_{2.5}$ and PM_{10}, both induced similar cytotoxic effects at 40% survival. PM_{10}-SE and $PM_{2.5}$ -SE induced dose-dependent responses. In general, the northern samples had a higher cytotoxic effect than the southern samples. **Apoptosis (J774A.1):** Northern samples induced more apoptosis than did the southeastern samples. There was no difference between PM_{10} and $PM_{2.5}$ induced apoptosis. **TNF-α and IL-6 (J774A.1):** TNF-α and IL-6 induced dose-dependent increases. At 80 µg/cm^2, PM_{10} -SE induced the most production of IL-6 followed by $PM_{2.5}$ -SE, PM_{10}-N , and $PM_{2.5}$ -N. **J774A.1 Supernatant Toxicity (L929):** Conditioned medium from J774A.1 pre-exposed to each PM type reduced cell viability in L929 cells. This was correlated with TNF-α level in supernatants.

Reference: Penn et al. (2005, 088257) **Species:** Human **Cell Type:** BEAS-2B	BDS: Butadiene soot (created on-site by passing BD through a back-flash protected stainless steel two-stage regulator to a stainless steel Bunsen burner) -P1: <2.5 µm -P2: 2.5-10 µm -P3: >10 µm BDS-W: solvent washed Graphite Composition: <2.5 µm = 92%, 2.5-10 µm = 5%, >10 µm = 3% **Particle Size:** BDS-P1: <2.5 µm; BDS-P2: 2.5-10 µm; BDS-P3: >10 µm	**Route:** Cell Culture (1-1.5×10^6 cells) **Dose/Concentration:** 3 mg BDS **Time to Analysis:** 5 min-72 h	**Particle Characterization:** By weight, EC makes up 94% of BDS, hydrogen 2%, nitrogen and sulfur 1%, and oxygen less than 0.1%. **PAH Components of BDS: 13 prominent PAHs:** acenaphthylene, fluorene, anthracene, cyclopentaphenanthrene, fluoranthene, acephenanthrylene, pyrene, benzofluorenes, acepyrene, chrysene, benzopyrenes, perylene, benzoperylene. **BDS Activity:** At 60-120 min, BDS was observed in the cells. At 4 h, fluorescence observed in cytoplasmic vesicles and increased during the first 24 h then plateaued for the next 72 h. BDS-W appeared in vesicles sooner than BDS.
Reference: Pozzi et al. (2005, 088610) **Species:** Mouse **Cell Type:** RAW 264.7	PM: Collected continuously for 15 days, 8-10 m from street, Sept 1999, Rome, Italy -F = Fine particulate -C = Coarse particulate CB (Degussa Huber NG90) **Particle Size:** PM-F: 0.4-2.5 µm; PM-C: 2.5-10 µm; CB: 200-250 nm	**Route:** Cell Culture (1.3×10^5 cells/well) **Dose/Concentration:** 30 µg/mL; 14 µg/cm^2 120 µg/mL; 54 µg/cm^2 **Time to Analysis:** 5, 24 h	**Cytotoxicity:** For 24 h, lower levels of PM-F, PM-C, and CB had no effect on cell viability. Higher levels of PM-C and CB induced a significant release of LDH. **Arachidonic Acid (AA):** Both fractions of PM increased AA release in a dose-dependent manner at 5 h. CB increased a release only at the higher concentrations although, in terms of magnitude, the CB-induced release was much less than the ambient PM-induced release. Pretreatment with deferoxamine was not effective in decreasing AA release. **TNF-α:** TNF-α levels increased significantly for both concentrations and time periods for PM. PM-C at 24 h was significantly lower than at 5 h for both concentrations. PM-C at 30 µg/mL induced a much greater TNF-α release than PM-F at 5 h. **IL-6:** PM-F significantly increased at 5 h for both concentrations. Elevated IL-6 levels were exhibited at both PM-C doses at 24 h. At 5 h, only the high dose elevated IL-6 levels. CB was devoid of an effect on IL-6. LPS-induced IL-6 response was similar to coarse PM at the high dose, with the response being greater at 24 h than at 5 h.
Reference: Prophete et al. (2006, 156888) **Species:** Rat **Cell Type:** NR8383 AMs	Ambient $PM_{2.5}$ NYC: 1st and 26 St, NYC LA: San Gabriel foothills, Claremont, CA SEA: 15th Ave S and S. Charleston, Seattle, WA V, Mn, Al, Fe levels in PM added metals to cells V: Na_3VO_4 Al: $AlCl_3•6H_2O$ Mn: $MnCl_2•4\ h_20$ Fe: $FeCl_3•6H_20$ **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture (2×10^5 cells/mL) **Dose/Concentration:** Fe(III) 16 µmol V, Mn, and Fe(III) mixtures with V or Mn in molar ratios 0.02, 0.08, 0.2 and 0.4 × Fe(III) Al and Fe(III) mixtures with Al in molar ratios 0.37, 0.75, 2, 7.5 × Fe(III) **Time to Analysis:** 20 h	**Particle Characterization:** Fe and metal to F ratios based on ratios observed in $PM_{2.5}$ from LA, SEA and NYC sites. V: Fe ratios remarkably similar among sites. Fe levels fixed at NYC level of 16 µm (highest). **IRP:** Coexposure with 3 metals increased IRP binding activity relative to Fe(III) alone, by up to 3.5 fold for Al (1.5-3 ratio), 2 fold for Mn (0.08-0.2 ratio) and 7 fold for V (0.2 ratio). IRP activity dropped at higher ratios. A drop in IRP activity at higher ratios may be result of cytotoxicity for Al, but not for V and Mn. **iNOS:** Al induced iNOS expression dose-dependently. There was no observed effect for Mn and V. **Induction of Hypoxia-inducible Factor (HIF-1α):** Only V and Al induced HIF-1α. **Activation of ERK1 and -2:** V and Al induced pERK1, but only V induced pERK2. Mn had no increasing effects, but data indicated a decreasing induction.

Study	Pollutant	Exposure	Effects
Reference: Ramage and Guy (2004, 055640) **Species:** Human **Cell Type:** A549	PM_{10}: Collected in Wolverhampton, UK ufCB: Ultrafine Carbon Particles (Origin not reported) **Particle Size:** PM_{10}, ufCB: <100 nm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 80 µg/mL **Time to Analysis:** 0, 0.5, 3, 6, 18 h	**CRP:** Treatment with ufCB or PM_{10} produced an increase in CRP expression with similar effects noted after 6 h. PM_{10} induced greater increases than ufCB. Both the cytoplasm and nucleus contained CRP. **Hsp70:** PM_{10} and ufCB induced increased levels at all time points with ufCB inducing greater levels than PM_{10}. Hsp70 expression was observed in the cytoplasm and nucleus. **Antioxidants of CRP and Hsp70:** Coincubation of ufCB with Nacystelin and Trolox caused a small reduction in CRP and Hsp 70.
Reference: Rao et al. (2005, 095756) **Species:** Rat **Strain:** SD **Cell Type:** AMs and cultured lung fibroblasts	DEP: SRM 2975 (NIST) **Particle Size:** 0.5 µm	**Route:** Cell Culture **Dose/Concentration:** 200 µg/mL **Time to Analysis:** 4 h	**mRNA Expression:** No change in IL-1β or iNOS were observed. Data suggests that the lung fibroblasts is the main source of IL-6 and MCP-1 in BAL fluid because of their comparatively high message levels. Due to the extreme variability in results, the cause of an increase on co-culture with AMs and/or DEPs was not assessed.
Reference: Reibman et al. (2003, 156905) **Species:** Human **Cell Type:** HBEC, BEAS-2B	UFPM: Ultrafine PM FPM: Fine PM IPM: Intermediate PM CPM: Coarse PM CB: Carbon black All PM collected 8th floor, 26th St and 1st Ave, New York City, NY **Particle Size:** UFPM: <0.18 µm; FPM: 0.18 - 1.0 µm; IPM: 1.0 - 3.2 µm; CPM: >3.2 µm	**Route:** Cell Culture **Dose/Concentration:** 11 µg/cm^2; 100 µg/mL **Time to Analysis:** 6, 18 h	**Cytotoxicity:** After treatment, cells were more than 90% viable. UFPM and FPM caused no gross alterations in cell morphology or adhesion. **MIP3α/CCL20 mRNA (6 h):** Stimulation of mRNA released by HBEC upon exposure to UFPM appeared similar to that provided by TNF-α (5 µg/mL) and IL-1β (10 mg/mL). **MIP3β/CCL20 protein in HBEC (18 h):** TNF-α and IL-1β induced a dose-dependent increase in MIP3α/CCL20 protein (0-10 ng/mL), whereas Il-4 and IL-13 induced MIP3α/CCL20 protein release that reached maximum levels at 1 ng/mL. No release of MIP1α/CCL3 nor RANTES/CCL-5 was observed upon stimulation with cytokines. **Secretion of MIP3α/CCL20 in response to PM (18 h):** All PM fractions less than 2.5 µm resulted in the release of MIP3α/CCL20 protein in HBEC roughly equivalent amounts. CB similar in size to UF/fine PM did not result in the release of MIP3α/CCL20, nor did LPS (0.01-1.0 µg/mL). No release of MIP1α/CCL3 nor RANTES/CCL 5 was observed upon stimulation by PM fractions. **Activation of MAPK (ERK1/2 and p38):** ERK1/2 and p38 was activated by TNF-α, IL-1β, IL-4 and IL-13 within 15 min and was sustained for at least 60 min. Erk1/2 and p38 inhibitors reduced MIP3α/CCL20 release in BEAS-2B cells in response to cytokines.

Study	Pollutant	Exposure	Effects
Reference: Riley et al. (2003, 053237) **Species:** Rat **Cell Type:** RLE-6TN (Type II Alveolar Epithelial Cells)	Zn: $ZnCl_2$ Cu: $CuCl_2$ Fe: $FeCl_2$ V: VCl_4 Ni: $NiCl_2$ **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 0.01, 0.1, 1.0, 10 mM **Time to Analysis:** 2, 4, 24, 72 h	**Cytotoxicity (SDH):** All particles were cytotoxic in a dose-dependent manner. Zn and V were cytotoxic at 0.05 mM, Cu at 0.5 mM, Ni at 0.8 mM and Fe at 2 mM. For Zn, cell death (LDH) had a biphasic response: a slow logslope until approx 0.1 mM at which point it rapidly accelerated to a peak at 5 mM with a small decline at 10 mM. Most of Zn cytotoxicity was not due to apoptosis. LPS did not affect either Zn or Cu cytotoxicity. **Metabolism Inhibition Time Course Response (Cu and Zn only):** At high (1 mM) concentrations, Zn toxicity peaked at 36-48 h followed by a 2-fold recovery by 72 h. Cu showed a faster, steady decline plateauing after 36 h. At low concentrations (0.1 mM), Cu showed a steady slow decline. At 48 h, Zn decreased faster to max activity and returned to control by 72 h. **IL-6 Secretion:** Zn and Cu both decreased IL-6 secretion. Decreases were very similar for both metals and concentrations when expressed as secretion per viable cell ratio except for Zn at 1.0 mM. **Metal Combinations:** Zn and Cu gave variable results. Zn protected against V cytotoxicity. Zn and Cu had an additive response. Zn did not affect Fe toxicity.
Reference: Riley et al. (2005, 096452) **Species:** Rat, Human **Cell Type:** RLE-6TN, NR8383 Alveolar Macrophages, A549	Fe: $FeCl_2$ Ni: $NiCl_2$ Cu: $CuCl_2$ V: VCl_2 **Particle Size:** NR	**Route:** Cell Culture (5×10^4 cells/well Alveolar Cells; 1.2×10^5 cells/well NR8383) **Dose/Concentration:** AMs: 0.02, 0.05, 0.07, 0.08 mM; RLE-6TN: 0.1, 0.2, 0.6, 1.0, 6.0 mM; A549: 0.5, 0.8, 4.4, 4.8 mM **Time to Analysis:** 2-48 h	**Relative Sensitivity of Cell Strains to Metal Chloride:** NR8383 was more sensitive than RLE-6TN and A549 except for V where NR8383 and RLE-6TN were both more sensitive than A549. **Relative sensitivity of Cell Strains to Metal Chloride vs Sulfate:** With the exception of Cr, sulfate was generally more cytotoxic than chloride (note V valence state). **A549 Cytotoxicity Time Course:** Zn cytotoxicity takes 24 h to develop whereas Cu cytotoxicity develops within 2 h. LDH release for Cu, however, develops in 24 h. **RLE Cytotoxicity Time Course:** Zn starts at 2 h and develops until 24 h. Cu develops within 2 h and continues until 24 h where it is less toxic than Zn. Both release equivalent amounts of LDH after 24 h. **NR8383 Cytotoxicity Time Course:** Both Zn and Cu exhibit time dependent toxicity beginning as early as 4 h. LDH release maximizes at 12 h and either remains steady or declines.
Reference: Ritz et al. (2007, 198901) **Species:** Human **Cell Type:** BEAS-2B, NHBEC	DX: Extract of DEP (generated from a light duty four-cylinder diesel engine 4JB1 type Isuzu Automobile) **Particle Size:** <1 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 0, 20, 50, 100 µg/mL **Time to Analysis:** 24 h	**NQO1 (Sentinel Phase II Enzyme):** Cells transfected with NQO1 reduced induction of IL-8 by DX exposure. **Sulfurophane:** Increased gene expression of phase II enzymes, particularly NQO1, was observed in both cell types. Gene expression in BEAS-2B was greater than that of NHBEC. Sulfurophane did not upregulate GSTM1 in BEAS-2B but induced a 2-fold increase in NHBEC. Pretreatment also inhibited DX-induction of IL-8 in both cell types. **Cytokines:** DX induced significant increase of IL-8 in both cell types at concentrations of 10 µg/mL or higher. GM-CSF and IL-8 remained unaffected in BEAS-2B. GM-CSF and IL-8 Increased in NHBECs and reached statistical significance at 25 µg/mL.

Study	Pollutant	Exposure	Effects
Reference: Rosas Perez et al. (2007, 097967) **Species:** Mouse **Cell Type:** J774A.1	PM_{10} Collected in Mexico City, Mexico from January-June, 2002 North: Iztacala, manufacturing industry; Center: Merced, heavy traffic; South: Ciudad Universitaria, residential Principal Component Analysis of Air Pollution Data: Group 1:S/K/Ca/Ti/Mn/Fe/Zn/Pb (43% of variance); Group 2: Cl/Cr/Ni/Cu (16%); Group 3: Endotoxins/OC/EC (14%). For all 3 sites: Averages of Group 1 is statistically different among the center, north and south sites with the central site producing the highest values. Group 2 is similar among the sites and, for Group 3, the north had a lower average than the center and south sites. **Particle Size:** PM_{10}	**Route:** Cell Culture (1.5×10^4 cells/cm^2) **Dose/Concentration:** 20, 40 or 80 µg/cm^2 **Time to Analysis:** 72 h	**Cytotoxicity:** Responses were dose-dependent; there was no observed site interaction. Cytotoxicity seems to be a result of the following components: S/K/Ca/Ti/Mn/Fe/Zn/Pb. **IL-6:** Only the center site at 40 µg/cm^2 induced an increase. Induction of higher IL-6 levels seems to be related to high values of S/K/Ca/Ti/Mn/Fe/Zn/Pb and endotoxins/OC/EC. **TNF-α:** Production was induced by all samples in a dose-dependent manner. Similar to IL-6, induction of higher TNF-α levels seems to be a result of high values of S/K/Ca/Ti/Mn/Fe/Zn/Pb and endotoxins/OC/EC. **p53:** Only south PM had effect. Induction of p54 seems to depend on high levels of Cl/Cr/Ni/Cu and low levels of S/K/Ca/Ti/Mn/Fe/Zn/Pb.
Reference: Sakamoto et al. (2007, 096282) **Species:** Human **Age:** 58-82 yr (Smokers) **Cell Type:** HBEC	PM_{10}: EHC-93 (Obtained from Health Canada, Canata) **Particle Size:** PM_{10}	**Route:** Cell Culture **Dose/Concentration:** 100, 300 and 500 µg/mL **Time to Analysis:** Calcium responses: up to 60 min; cytokines: 6 or 24 h	**Intracellular [Ca2+]:** [Ca] concentration slowly increased, elevating after 10 and 30 min for 500 and 300 mg/mL, respectively. The response plateaued at 35 min for 500 µg/mL. **Extracellular [Ca2+]:** Starting at 20 min, the removal of extracellular Ca decreased the PM_{10} response significantly. Calcium channel blocker (10µM or 1mM) LaCl3 and (5mM) NiCl2 significantly blocked the PM-induced intracellular Ca. Lacl2 administration (1mM) inhibited the PM-induced Ca2+ response in a dose-dependent manner. **Mode of Action:** Intracellular Ca induced by ATP declined more slowly in the cells exposed by PM_{10}. This indicates that PM_{10} blocks Ca clearance via the calcium pumps. **Cytokines:** PM_{10} induced a dose-dependent increase in cytokine mRNA levels and cytokines IL-1β, LIF, IL-8 and GM-CSF. Cytokine expression was unaffected by the reduction of extracellular Ca2+ . Preincubation with the calcium chelator reduced responses for IL-1β and IL-8 but not LIF or GM-CSF.
Reference: Salnikow et al. (2004, 087469) **Species:** Human **Cell Line:** 1 hAEo-	$FeSO_4$ $FeCl_3$ $NiSO_4$ **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 0.25 and 0.5 mM Fe exposures also contained 60 µg/mL apotransferrin **Time to Analysis:** 24 h	**Cytotoxicity:** Both Fe had no effect. $NiSO_4$ caused marginal cytotoxicity (75%). **Hypoxic Stress:** At 20 h, $NiSO_4$ (at concentrations of 0.25 or 0.5 mM) induced NDRG-1/Cap43 protein production indicating hypoxic stress. DFX and DMOG induced a similar effect. **IL-8:** $NiSO_4$ induced IL-8 time-dependently for up to 48 h. At 48 h, the increase was 6+ fold. **Coexposure (Ni + Fe) on Fe uptake:** Fe(III) uptake was greater than Fe(II) uptake. $NiSO_4$ had no effect. Ni uptake was greater than Fe uptake but was decreased by coexposure to Fe. Coexposure also did not effect hypoxic stress. Coexposure with Fe did reduce Ni-induced IL-8 production.

Study	Pollutant	Exposure	Effects
Reference: Salonen et al. (2004, 187053) **Species:** Mouse **Cell Type:** RAW 264.7	PM_{10} (urban traffic) Finland Pooled as winter (W), spring I (SI), or spring II (SII) based on component/time considerations **Particle Size:** PM_{10}: 0.12-10 µm	**Route:** (2×10^6 cells/well) **Dose/Concentration:** 15, 50, 150, 500, 1000 µg/mL **Time to Analysis:** 0, 24 h	Air quality parameters: Winter and spring I did not differ. SII much lower $PM_{2.5}$ Metal data equivocal as well as highly variable resuspension rates. Total PAHs: W=303; SI=233; SII=204 ng/mg **Inflammation (IL-6, TNF-α, NO)/Cytotoxicity:** A dose-dependent increase was observed for TNF-α, IL-6 and NO except for SI. The IL-6 levels, of those particles exposed to SI, decreased at 1000 µg/mL. **TNF-α, IL-6:** SI = SII>>W>control. **NO production:** W≥SI≥SII **Cell Viability:** W=SI=SII toxic at 500 and 1000 µg/mL **Water-soluble vs Insoluble:** TNF-α and IL-6 were nearly entirely the result of insoluble components of PM_{10}. Cytotoxicity was driven by both soluble and insoluble components. **Metal Chelation:** The addition of metal chelators did not modify IL-6, TNF-α or cytotoxicity **LPS inhibitor:** Treatment with the LPS inhibitor eliminated the IL-6 response and, perhaps, slightly reduced the TNF-α response but not cytotoxicity **Hydroxyl radicals:** A dose-dependent induction of hydroxyl radicals and induction of hydroxyl radical lesions (at 500 and 1000 $\mu g/m^3$) in the calf thymus DNA were observed.
Reference: Samet et al. (2003, 113782) **Species:** Human **Cell Type:** A431 (Epidermoid Cells)	As: $NaASO_3$ V: $VOSO_4$ Zn: $ZnSO_4$ **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 500µM **Time to Analysis:** 20, 30 or 90 min	**EGFR Dimerization:** Zn, V or As did not induce EGFR dimerization in a cell free system i.e., no direct crosslinking. Zn did not induce dimerization in whole cells either. **Phosphorylation of EGFR:** Zn induced phosphorylation at 3 sites similar to EGF. As and V had no effect. **EGFR Kinase Inhibitor:** While EGF action was blocked, Zn continued to induce phosphorylation and was independent of EGFR kinase activity. **c-Src:** Blocking of c-Src tyrosine kinase (transactivator of phosphorylation) negated all Zn-induced phosphorylation but only had a slight effect on EGF stimulated cells. **ERK1/2 Phosphorylation:** Zn increased levels of ERK1/2. Pretreatment with EFGR kinase inhibitor reduced both Zn and EGF effect. This effect was not blocked by the c-Src blocker.
Reference: Santini et al. (2004, 087879) **Species:** Mouse **Cell Type:** RAW 264.7	DEP: Collected adjacent to moderate traffic in Rome, Italy **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture (2.5×10^5 cells/mL) **Dose/Concentration:** 0.01, 0.1, 1.0 µg/mL **Time to Analysis:** 24 h	**500 MHz Results (no 1 µg/mL):** DEP induced a dose-dependent increase in choline compounds, α- and βgamma- glutamine/glutamate (0.01 >0.1 µg/mL), lactate, and CH_2, CH_3 moieties of fatty acids. DEP decreased inositol and phosphoreatinine. **700 MHz Results (no 1 µg/mL):** DEP induced similar results, except α-, βgamma-glutamine were dose-dependent. Inositol showed no effect. Taurine slightly increased. Results were confirmed after eliminating biological interferences via perchloric acid. **Growth Curves/Cell Cycle Analyses/Cell Morphology:** DEP had no effect. **Cytokines:** IL-6 levels increased at 0.1 and 1 µg/mL. TNF-α was unaffected.

Study	Pollutant	Exposure	Effects
Reference: Saxena et al. (2003, 096986) **Species:** Mouse **Cell Type:** RAW 264.7	DEP: SRM 1650 CO: Crude Organic Extract of DEP Fractionated into asphaltene (pentane/hexane), saturated hydrocarbon, less polar (aromatic) hydrocarbon, more polar (aromatic) hydrocarbon, resins, residual (resins) **Particle Size:** NR	**Route:** Cell Culture (2.5×10^4 cells/mL) **Dose/Concentration:** DEP, CO 5, 10, 15, 20, 25 µg/mL IFN-y: 10 ng/mL LPS: 1 mg/mL **Time to Analysis:** 1-3 days	**Cytotoxicity:** No cytotoxic effects were observed. **NO:** DEP alone induced NO in a dose-dependent manner which peaked after 1 day and plateaued for days 2 and 3. IFN-y + DEP showed dose- and time-dependency. LPS + DEP showed no effect at 1 day, but dose-dependently reduced NO production on days 2 and 3. Addition of Bacillus Calmette-Guerin (BCG) eliminated the effect of DEP at 2 days but showed a dose-dependent decrease at 3 days. **Effectiveness of Particulate Components:** The carbonaceous core of DEP did not affect BC G-stimulated NO production. CO significantly inhibited BCG-stimulated NO production. Study indicated that the extract of aromatic hydrocarbons and resins caused an inhibitory effect in a dose-dependent manner.
Reference: Seagrave et al. (2007, 097549) **Species:** Human **Gender:** Male (3 donors) **Age:** 16, 23 yr **Cell Type:** A549	DE: Generated by DE 5500 watt generator using #2 certification oil performed under 5000w load. Emissions diluted to 3 mg/m^3 total particulate matter. **Particle Size:** 0.14-0.5 µm	**Route:** Air Liquid Interface **Dose/Concentration:** 8.33 mL/min/well **Time to Analysis:** 3 h exposure; 1 or 21 h post-exposure	**Particle Deposition:** 140 and 500 nm microspheres demonstrated uniform deposition of approx. 10%. **Transepithelial Electric Resistance:** No effect of DE; rather, more effect was observed from air controls. **Macromolecular permeability:** DE caused an increase 1 h but returned to control at 21 h. **LDH/Cytotoxicity:** DE had a highly variable(donor specific) effect at 1 h and returned to control levels at 21 h **Mitochondrial activity (WST):** DE reduced activity at 1 h and possibly increased activity at 21 h (high donor-to-donor variability) **Mucus Like Substance Excretion:** There was high donor to donor variability; no overall effects were observed. **Alkaline Phosphatase (AP):** DE decreased at 1 h and perhaps increased at 21 h **Glutathione:** DE caused a large decrease at 1 h but returned to normal at 21 h. **HO-1:** After DE exposure, levels increased but were still lower than air exposed controls **Cytokines:** No differences for IL- 8 or 12, TNF-α, GM-GSF, IL-1α, or IFN-γ were observed. IL-4 and -6 were decreased upon DE exposure.
Reference: Seagrave et al. (2004, 087470) **Species:** Human **Cell Type:** A549	DPM: SRM2975 (NIST) DPM-O: DPM organic extract (acetone/DCM) CB: Carbon Black (Elftex-12, Cabot) **Particle Size:** CB: 37 nm; Stokes diameter 198 nm	**Route:** Cell Culture (1×10^5 cells/well) **Dose/Concentration:** 0.03 -1,000 $\mu g/cm^2$ **Time to Analysis:** 0, 18 h	**IL-8 release:** DPM increased semi dose-dependently (perhaps steady based on error range) up to 1 $\mu g/cm^2$ after which IL-8 declined dose dependently to zero (control = 100%) at 300 and 1000 $\mu g/cm^2$. LDH release was steady which indicates no cytotoxicity. **DPM interaction with IL-8:** DPM depletes IL-8 from solution in a dose-dependent manner (cell free). BSA preincubation reduced the slope of the dose response but not the final result. CB has no effect. DPM-O residuals act identical to DPM. Increasing NaCl concentrations reduced DPMs depletion of IL-8 **Neutrophil responses:** DPM and bound IL-8 together caused a marked aggregation of cells resulting in spindle shapes. DEM or IL-8 alone did not cause this aggregation although DEP did recruit neutrophils

Study	Pollutant	Exposure	Effects
Reference: Seagrave et al. (2003, 054979) **Species:** Human, Rat **Cell Line:** F344/Crl BR (mouse) **Age:** 11 wk (mouse) **Weight:** 250 g **Cell Type:** A549, AMs	PM filter collection Collected from diesel or gasoline powered vehicles as follows: BG: BS Gasoline G30: Normal Emitter gasoline (30F) G: Normal emitter gasoline (72F) HD: High Emitter Diesel D30: current technology diesel (30F) D: current technology diesel (72F) WG: White Smoke Gasoline **Particle Size:** NR	**Route:** Cell Culture (1×10^5 cells/well) **Dose/Concentration:** 0.03-10,000 µg/cm^2 **Time to Analysis:** 16-18 h	**Cytotoxicity:** LDH activity increased in A549 cells. The types of pollutants that are most toxic, in decreasing order of cytotoxicity, are the following: BG, G30, and G which are significantly different from HD, D30, D, WG which are also significantly different from DS. LDH activity also increased in rat macrophages. G, G30, and BG were the most toxic. HD and D30 were intermediately toxic and D, WG, and DS were the least toxic. In both cell types, gasoline was more cytotoxic than diesel. **Cytokines:** All particle types except DS increased IL-8 levels in A549 though not all increases were statistically significant. Also, many particle samples at high concentrations produced an apparent suppression of IL-8 release. **Alkaline Phosphatase:** G30 and G were more potent than the other particle samples in A549. WG and D30 induced no significant effects. For A549 cells, activity increased at low concentrations and was suppressed at higher concentrations. **Macrophage Peroxide Production:** In rat AMs, peroxide production was often the highest at the lowest concentrations and the lowest production caused by the highest concentrations. D30 followed this trend and induced the highest production as well as the greatest suppression. Using two different statistical methods, D30 >6 others which in turn >DS. Using the second method D30 and D >all other 6. Order of potency between two methods completely different. Authors noted that in vitro potency quite different from in vivo potency (previous paper).
Reference: Seaton. et al. (2005, 198904) **Species:** Human **Cell Type:** A549	$PM_{2.5}$ from London PM_{10} from Manchester (positive control) PM from Holland Park, Hampstead and Oxford Circus stations (HP, HR and OC) **Particle Size:** $PM_{2.5}$, PM_{10}, Holland Park, Hampstead and Oxford Circus PM had a median diameter of 0.4 µm. 80% of the particles had a diameter less than 1 µm.	**Route:** Cell Culture **Dose/Concentration:** 1-100 µg/mL **Time to Analysis:** Cytotoxicity: 24 h; IL-8: 8 h; Generation of hydroxyl radicals: 8 h	**Cytotoxicity:** Dust from all three tunnels (Holland Park, Hampstead and Oxford Circus) were able to cause cell death (LDH). The release of LDH indicated a dose-dependent relationship. The highest dose of Holland Park PM induced the ~17% release of LDH, Hampstead triggered ~ 13% and Oxford Circus ~3% (no different than control). PM_{10} from Manchester caused a 7% LDH release at the highest dose. The negative control (TiO_2) caused no response (2% release at highest dose). **IL-8:** All three tunnel PMs induced a dose-dependent release of IL-8. At the highest dose, all three tunnel dusts induced IL-8 stimulation more so than the control site $PM_{2.5}$. HP induced a 3 fold increase. Also, the highest TiO_2 concentration caused the least IL-8 stimulation. **Hydroxyl Radical Generation/ DNA Plasmid assay:** The plasmid assay indicated that the tunnel dusts induce more free radical activity than the Manchester PM_{10} and TiO_2. HP nearly doubled the percentage of DNA damage with intermediate results for HR and OC. Results for PM_{10}, TiO_2 and control were identical

Study	Pollutant	Exposure	Effects
Reference: Singal and Finkelstein (2005, 198905) **Species:** Human, Mouse **Cell Type/Line:** A549Luc1 lung adenocarcinoma epithelial cell line (human), MLE15Luc1 and MLE15Luc2 (mouse) All cells contain human cytokine IL-8 controlling firefly luciferase	AE2: Aerosil 200, amorphous silica (Degussa) CI: Carbon iron particles (25% Fe) **Particle Size:** AE2: 12 nm surface area ~200 ± 25 m^2/g; CI: ~40 nm	**Route:** Cell Culture (5×10^5 cells/well) **Dose/Concentration:** 18 µg/mL, 36 µg/mL, 72 µg/mL all in 1 mL /well **Time to Analysis:** 24 h	**Luc Activity:** Luciferase enzyme activity is significantly less in MLE15Luc2 cells than in MLE15Luc1 cells. For both cells, luciferase activity is time- and dose-dependent peaking at 4-8 h. **Aerosil 200:** AE2 induced dose- and time-dependent Luc response which peaked at 3 h and decreased thereafter in a similar way as TNF-α. Contrary to TNF-α, AE2 induced much cytotoxicity starting at 6 h. **Effect of Proteasomal Inhibitors (MG-132):** Inhibitor reduced AE2 Luc activity to near control levels. Similarly, LDH-cytotoxicity was halved **A549 Human Cell Response:** AE2 acted similarly to the MLE response. CI particles showed slightly less activity without peaks. AE2 increased cytotoxicity after 12 h, whereas CI had no effect. Contrary to MLE mouse, MG_132 did not affect Luc activity but PD98059 (selective noncompetitive inhibitor of the MAP pathway) and SN50 (NF-κB inhibitor) reduced AE2 and CI-induced activity.
Reference: Song et al. (2008, 156093) **Species:** Rat **Cell Type:** RAW 264.7	DEP collected from a 4JB1-type, light-duty (2740 cc), four-cylinder diesel engine operated using standard diesel fuel at speeds of 1500 rpm under a load of 10 torque. **Particle Size:** 0.4 µm (mean diameter)	**Route:** Cell Culture (5×10^5 cells seeded on a 24-well plate) **Dose/Concentration:** 50 µg/mL **Time to Analysis:** 72 h	**Nitrite Production:** 50 µg/mL of DEP induced production when compared to the control. Over the 72 h period, a general trend was not observed, but maximal induction of nitrite occurred at 4 h after stimulation.
Reference: Steerenberg et al. (2006, 088249) **Species:** Rat, Human **Cell Type:** AM (rat), Type 2 cells (rat), A549	PMC: PM Coarse PMF: PM fine Ambient air samples collected from Rome, Italy; Oslo, Norway; Lodz, Poland; Amsterdam, the Netherlands; De Zilk, the Netherlands. **Particle Size:** PMC: 2.35-8.5 µm; PMF: 0.12-2.35 µm	**Route:** Cell Culture **Dose/Concentration:** NR **Time to Analysis:** 20 h	Crustal material (metals and endotoxin but not Ti, As, Cd, Zn, V, Ni, Se) were positively associated with AM IL-6 and TNF-α and Type 2 MIP-2 and IL-6. Sea spray (Na and Cl) was also correlated with AM IL-6.
Reference: Tal et al. (2006, 108588) **Species:** Human **Cell Type:** HAEC	100 mM Zn(II) or V(IV) stock solutions **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 500 µmol **Time to Analysis:** 5, 20 min	**Zn-mediated EGFR Phosphorylation:** EGFR kinase activity was required but not EFGR ligand binding. EGFR Kinase inhibition reduced Zn mediated EGFR activation. (authors NOTE: complete reverse of results in B82L and A431 cells). Src Kinase is not required. Zn inhibiting Src kinase was nearly total after 20 min. **EGFR-Specific Protein Tyrase Phosphatase (PTP):** Zn inhibited PTPs, similar to V(IV) resulting in a decrease of exogenous EGFR dephosphorylation
Reference: Tamaoki et al. (2004, 157040) **Species:** Human **Cell Type:** HBEC	UFCB: Ultrafine Carbon Black - (Tokai Carbon, Japan) FCB: Fine Carbon Black (Tokai Carbon, Japan) **Particle Size:** UFCB: 11 ± 0.5 nm (mean diameter) FCB: 250 ± 16 nm (mean diameter)	**Route:** Cell Culture (10^4 cells/well) **Dose/Concentration:** 6.1, 12.3, 18.4, 24.5, 30.7 µg/cm^2 **Time to Analysis:** Up to 72 h	**DNA Synthesis/ Protein Synthesis:** Synthesis increased by UFCB (30.7) for up to 72 h and flattened after 48 h. FCB had no effect. UFCB also showed a dose-dependent response beginning at 12.3 µg/cm^2 up to 24.5 after which the response plateaued. The addition of Cu/Zn Super oxide dismutase (SOD) or a NADPH oxidase inhibitor completely inhibited the UFCB effects. Similarly, two different EGFR tyrosine kinase inhibitors, and a Me inhibitor all reduced UFCB response to control levels. **ERK activation:** UFCB caused phosphorylation of ERK beginning at 2 min, peaking at 5 min and decreasing at 10 min. ERK activation was inhibited by EGFR tyrosine kinase inhibitor Cu/Zn SOD and neutralizing body for HB-EGF but not by PDGF-R kinase inhibitor. **HB (polyclonal heparin binding)-EGF release:** UFCB induced rapid cell surface loss with recovery after 20 min and nearly full recovery at 360 min. Metalloproteinase inhibitor and Cu/Zn SOD both prevented HB-EGF release.

Study	Pollutant	Exposure	Effects
Reference: Tao and Kobzik (2002, 157044) **Species:** Rat **Cell Type:** RLE-6TN (Alveolar Type II Epithelial Cells), Fetal Lung Fibroblasts (RFL), AMs	UAP: Urban Air Particles (SRM 1649) TiO_2 SiO_2 ROFA **Particle Size:** TiO_2: ~1 µm; SiO_2: ~1 µm; ROFA: NR	**Route:** Cell Culture (1×10^5 cells AM 1.4×10^5 cells RLE/RFL) **Dose/Concentration:** 1-50 µg/mL **Time to Analysis:** 24 h	**Cytokines:** TNF-α and MIP-2 in RLE was unaffected by any particle samples. TNF-α and MIP-2 in AM significantly increased with 25 µg/mL UAP. TNF-α and MIP-2 in the co-culture of AM + RLE increased with each particle. The order of particles in decreasing order are as follows: SiO_2 at 25µg/mL, UAP at 12.5 µg/mL, ROFA at 25 µg/mL, and TiO_2 at 50 µg/mL. Except for SiO_2, the blocking of effects caused by LPS absorbed on the particles did not affect the cytokine response. For SiO_2, the response was reduced but still above the control. **Co-culture:** Physically separating AM and RLE cells and adding PM completely negated the co-culture's response to PMs. This indicates that cell to cell contact is required for co-culture potentiation of PM effects. **Inhibitors:** Various inhibitors of cell adhesion molecules (heparin, β -1, 2 or 3 integrin) had no effect on UAP-induced cytokine release.
Reference: Veranth et al. (2007, 090346) **Species:** Human **Cell Type:** BEAS-2B, A549, NHBE	Artificial particles and PMs N-Al: nano alumina Al_2O_3 M-Al: Micro Al_2O_3 N-Ce: nano CeO_2 M-Ce: micro CeO_2 N-Fe: nano Fe_2O_3 M-Fe: micro Fe_2O_3 N-Ni: nano NiO M-Ni: micro NiO N-Si: nano SiO_2 M-Si: micro SiO_2 N-Ti: nano TiO_2 M-Ti: micro TiO_2 KLN: kaolin MUS: Min-U-Sil (ground crystalline silica) DD: desert rural soil Utah $PM_{2.5}$ JE: Juarez, urban street $PM_{2.5}$ MNC: Mancos, rural Utah $PM_{2.5}$ LPS: lipopolysaccharide V: $VOSO_4$ (soluble) (19 µg/mL) **Particle Size:** (Surface mean diameter) N-Al: 6 nm (261 m^2/g) M-Al: 210 nm (7.7 m^2/g) N-Ce: 14 nm (71 m^2/g) M-Ce: 1500 nm (0.6 m^2/g) N-Fe: 5 nm (221 m^2/g) M-Fe: 100 nm (12 m^2/g) N-Ni: 6 nm (145 m^2/g) M-Ni: 16 nm (57 m^2/g) N-Si: 19 nm (127 m^2/g) M-Si: 440 nm (5.4 m^2/g) N-Ti: 6 nm (242 m^2/g) M-Ti: 410 nm (3.5 m^2/g) KLN: 100 nm (24.3 m^2/g) MUS: (NOS <5 µm) DD: 400 nm (6.2 m^2/g) JE: (NOS <3 µm) MNC: 200 nm (13.0 m^2/g)	**Route:** Cell Culture (35,000 cells/cm^2 BEAS; 2500 cells/cm^2 NHBE; 20,000 cells/cm^2 A549) **Dose/Concentration:** 0.53, 5.3 and 53 µg/cm^2 (= 1, 10, 100 µg/mL) **Time to Analysis:** 24 h	**Cell Viability:** Except for Ni and V no cytotoxicity was observed at the highest concentration. **IL-6 Secretion in BEAS-2 B Cells:** Nano and micro sizes of the same metal showed no differences in response (high experiment to experiment variability). In general, the soil-derived dusts (JE, DD, MNC) were more potent than the metal and ceramic oxide particles. In KGM media, BEAS-2B cells are more responsive to vanadium and other soluble metals and less responsive to LPS, but this relationship is reversed in LHC-9 media. **IL-8 Secretion in BEAS/LHC vs NHBE in BEGM Cells:** Levels were much higher in NHBE cells than BEAS-2B cells. For BEAS-2B, the nano size Si and both sizes of Ni induced levels statistically greater than the control. For NHBE, only Si and Ni (for both sizes) were statistically greater than control. **IL-6 in NHBE:** The nano and micro sized particles of Al, Ce, Fe and nano sized Si all induced statistically significant increases. Control levels of IL-6 were much higher in NHBE cells than in BEAS-2B cells. Secretion induced by pure oxide particles was small for both the mid and high concentration levels (5.3 and 53 µg/cm^2). **BSA/ Bovine Serum Addition Effect:** In a fixed solution nano-Ni, nano-Ti and KLN all reduced the measured IL-6 by 60+ percent. Addition of BSA or bovine serum dose dependently reduced the action of the particles to near control levels. **PM Effects (without added protein) on IL-6 In Solution:** Increasing metal concentration did not affect a fixed IL-6 concentration until the 100 or 316 µg/mL levels.

Study	Pollutant	Exposure	Effects
Reference: Veranth et al. (2007, 090346) **Species:** Human, mouse, rat **Cell Type:** A549, BEAS-2B (types E and U), RAW 264.7, Primary macrophages	S: desert dust (collected from unpaved desert road in Utah, $PM_{2.5}$ enriched) V: vanadium soluble (prepared from $VOSO_4$, Alfa Aesar, Ward Hill, MA) C: Coal fly ash ($PM_{2.5}$ enriched and derived from commercial power plant burning Utah bituminous coal) D: Diesel PM (tail-pipe particles collected from high emitting BSr on-road light duty truck) L: Lipopolysaccharide T: Titanium dioxide (Alfa Aesar) K: Kaolin (purchased from Capitol Ceramics, UT) **Particle Size:** BET surface (m^2/g) S: 6.2 ($PM_{2.5}$ enriched) V: NA C: 5.4 ($PM_{2.5}$ enriched) D: NR L: NA T: 3.5 (1-2 µm) K: 24 (<200 mesh = 74 µm)	**Route:** Cell Culture **Dose/Concentrations:** Maximum concentrations: S = 100 µg/cm^2 V = 100 µg/cm^2 C = 100 µg/cm^2 D = 32 µg/cm^2 L = 1000 EU/mL T = 100 µg/cm^2 K = 100 µg/cm^2 **Time to Analysis:** 24 h	**Viability:** Generally, cell viability was greater than 75% of the control post treatment. Vanadium, at the highest concentration, induced less than 50% of control viability whereas kaolin, also at the highest concentration, induced cell death. **IL-6:** BEAS-2B E or U in LHC-9 showed a response to S and L. BEAS-2B (U) was in LHC-9 medium with added serum (FBS). This resulted in a doubling of response coupled with at least an 8 fold increase in control levels. BEAS-2B (E) showed response for S and V but not L. A549 showed response to S and K. RAW 264.7 and Rat macrophages showed responses to S(very low) and L. In general, the IL-6 responses in A549 and RAW 264.7 were similar and significantly lower than the responses in rat macrophages or BEAS-2B. **Effect of Culture Media Composition (BEAS-2B):** Varying ratios of LHC-9 and KGM media resulted in a near 10 fold increase in control rate once LHC was 33% or more of the media. Upon Soil Dust (NOS) exposure IL-6 increased linearly with % LHC-9 in culture/exposure media. Addition of calf serum (0.1-10 %) raised control IL-6 levels at least 40 fold. At a steady PM concentration, the addition of serum resulted in a log-linear increase in IL-6 release which blocked any PM effect. **Reversibility of Media Effect:** Changing media with every passage showed that media effects do not persist once media are changed. **Culture Well Size:** Going from a 6 well to 96 well plate (decreasing well size) increased IL-6 control values about ten fold, while the positive control (TNF) response increased 3 fold. Hence the sensitivity of the test (i.e., positive/control response) declined from 11 fold to 3 fold with increasing well number / decreasing well size. Because cell seeding density and the like were held constant, these changes suggest that edge effects are the cause of the IL-6 changes.
Reference: Veranth et al. (2006, 087479) **Species:** Human **Cell Type:** BEAS-2B	$PM_{2.5}$ samples from 28 samples from 8 locations in Utah, New Mexico and Texas (rural, industrial, road side, military) 2 coal fly ash samples (a product of combustion using Utah bituminous coal and New Mexico bituminous coal) TiO_2 kaolin clay **Particle Size:** $PM_{2.5}$; TiO_2: 1-2 µm	**Route:** Cell Culture (35,000 cells/ cm^2) **Dose/Concentration:** 10, 20, 40, 80 µg/cm^2 **Time to Analysis:** 24 h	**Cell Assays:** In sample soils viability declined dose dependently while IL-6 increased dose-dependently. IL-8 was highly variable (peak at 20 µg/l, dose-dependent increase or flat response.) **IL-6 Assays for All Soil PMs:** Soils ranged across an order of magnitude greater than LPS, coal fly ash, TiO_2 or kaolin samples. One soil even exceeded the pos V control at equal concentrations **Correlation with Cell Viability:** Correlation was strong for Mn ($p<0.001$) and weak for EC3, K, Se, and Hg ($0.01<p<0.05$). **IL-6, 10 µg/cm^2:** Correlation was medial for OC-1(OC) and P at $0.001<p<0.01$. **IL-6, 80 µg/cm^2:** Correlation was strong for OC3, OP (pyrolized Carbon), OC, EC1, TC and intermediate for OC2, OC4, Zn and weak for Ca2+, EC2, Si, Ca, Ca: Al. **IL-8, 10 µg/cm^2:** Correlation was weak for EU (Endotoxin), CO_3, Si, and Br. **IL-8, 80 µg/cm^2:** Correlation was medial for CO_3, Sr and weak for K+, EC3, Mg, Si. **IL-8 trend (corr over 10-80 range):** Correlation was strong for EC, intermediate for OC4, EC1, EC2, EC3, TC, Ni and weak for OP, OC, Cr, and Sr. IL-6 and Il-8 were not correlated nor were IL-6 and cell viability. Authors noted that weak correlations ($0.01<p<0.05$) contained false positives.

Reference: Veranth et al. (2004, 087480) **Species:** Human **Cell Type:** BEAS-2B	$PM_{2.5}$ enriched soil samples DD: desert dust, unpaved road, Utah WM: West Mesa, sandy grazing site, NM R40: Range 40 gravel soil, TX UN: Uinta, sandy soil, UT **Particle Size:** 0.4-3 µm	**Route:** Cell Culture (20,000/cm^2) **Dose/Concentration:** 10, 20, 40, 80, 160 µg/cm^2 **Time to Analysis:** 24 h	**Elemental Analysis of PM**: Major differences UN generally lower in major minerals but high Fe content and high EC. High Mn. Low Pb and Zn **Cytotoxicity:** UN and WM were the most cytotoxic at all dose levels, followed by R40 and DD. All particles showed a dose-dependent cytotoxic response. **IL-6 Release:** DD and R40 (up to the 160 µg/cm^2) showed dose-dependent responses and induced an 8-fold increase at the highest concentration levels. WM peaked at 40 µg/cm^2 and UN induced similar responses above 10 µg/cm^2. **IL- 8 Release:** DD induced a dose-dependent response. WM peaked at 10 µg/cm^2. Release induced by DD and WM seemed to be limited by toxicity. There was no treatment with R40. **TNF-α:** DD, WM and UN induced release was not detected at the 40 or 80 µg/cm^2 concentrations. **LPS:** LPS was the primary factor in inducing IL-6 release when exposed to LPS-containing mixtures. LPS alone induced lesser responses than treatment to the environmental dust particles. TiLPS induced a less than two-fold increase in IL-6 versus the over seven-fold increase induced by soil dust positive control. LPS treatments were less cytotoxic than DD. Limited IL-6 and IL-8 responses were observed at 2000 EU/mL compared with DD at 80 µg/cm^2 **Endotoxin:** Inverse relationship between endotoxin content and IL-6 release was observed. **Viability vs Physical Modification of Dust Sample (no UN):** Only leaching in a variety of water based vehicles increased viability minimally (generally <25 %). Heat treatment (150-, 300, 550° F) and methanol extraction had no effect **IL-6 Release vs Physical Modification of Dust Sample (no UN):** One hour thermal treatment at 150° F had no effect on IL-6 response. All other treatments reduced IL-6 release (heat 350°, 500° and extractions).
Reference: Veronesi et al. (2002, 024599) **Species:** Human **Cell Type:** BEAS-2B	Ambient PM - St. Louis: Urban particulates - Ottawa: Urban particulates -MSH: Volcanic dust from Washington state's Mt. St. Helen -Woodstove: Woodstove particles from conventional fireplace burner -CFA: Coal fly ash from western U.S. power plant -OFA: Oil fly ash from Niagara, NY - A: Total Fractions - B: Soluble Fractions - C: Washed Fractions **Particle Size:** PM >2.5 µm; PM: 2-10 µm; PM >10 µm	**Route:** Cell Culture **Dose/Concentration:** 50 µg/mL; 30 µg/cm^2 100µg/mL; 60 µg/cm^2 **Time to Analysis:** 4, 16 h	**Ca:** Calcium increased significantly with all particles types. **IL-6:** At 50 and 100 µg/mL, IL-6 increased with all particle types at 4 and 16 h. Overall, fraction -A was the most potent. **Surface charge:** Surface charge correlated strongly with increases in both Ca^{2+} and IL-6 levels. OFA, however, was unmeasurable due to technical difficulties.

Reference: Vogel et al. (2005, 087891) **Species:** Human **Cell Type:** U937 (ATCC) monocytes (macrophage differentiation)	UDP: SRM 1649 (NIST) UDP-OE: DCM extract of SRM-1649, 0.45 µm filter sUDP: stripped particles UDP DEP: SRM 2975 (NIST) DEP-OE: DCM extract of SRM-2975, 0.45 µm filter sDEP: stripped particles DEP CB95: Carbon Black (Degussa) **Particle Size:** UDP, DEP: NR; CB95: 95 nm	**Route:** Cell Culture (2×10^5 - 2×10^6 cells/mL) **Dose/Concentration:** DEP, UDP: 2.5, 10 or 40 µg/cm^2 (eq to 12.5, 40, 200 µg/mL) DEP-OE, UDP- OE: 10 µg/cm^2 (particle equivalent) **Time to Analysis:** 24 h	**Effect On mRNA Expression (COX-2, TNF-α, IL-6, IL-8, C/EBPβ, CRP, CYP1a1):** All DEP and UDP induced dose-dependent increases. IL-6 tended to plateau at 10 µg/cm^2. Generally, with the exception of COX-2, UDP effects on genes were stronger than DEP. **Cytotoxicity:** Both DEP and UDP were cytotoxic at 40 µg/cm^2 **Fractionation and mRNA Expression:** For COX-2, TNF-α, IL-8 mRNA fractions were much more active than parent particles and consequently stripped particles were much less active than parent particles. CB95 had no effect. The reverse effect occurred for IL-6 and CRP mRNA expression. The particles that induced mRNA expression in decreasing order are: sUDP, UDP, UDP-OE. **Inhibition Of mRNA Expression:** CRP: pretreatment with IgG and wortmannin (Fcγ receptor binding and ingestion dependent inhibitors resp) blocked the effects of DEP, UDP and sDEP and sUDP. Luteolin (AhR inhibitor) had no effect. **COX-2:** Only luteolin inhibited COX-2 expression for DEP, DEP-OE, UDP, and UDP-OE. **CYP1a1:** Luteolin also inhibited OE-DEP and OE-DUP effects (only those two particles tested). **Cholesterol Accumulation:** DEP, UDP and UDP-OE and DEP-OE at 10 µg/cm^2 all increased cholesterol accumulation by at least 2 fold
Reference: Wang et al. (2003, 157106) **Species:** Rat **Cell Type:** Lung Myofibroblasts	V_2O_5: (Aldrich Chemical Co., Wisconsin) **Particle Size:** NR	**Route:** Cell Culture (1×10^5 cells/100 mm dish; 3.2×10^4 cells/cm^2) **Dose/Concentration:** 400 µm **Time to Analysis:** 0.5, 1, 4, 24 h	**H_2O_2 Drives STAT-1 Activation:** Pretreatment with NAC or catalase reduced V_2O_5-induced STAT activation by more than 90% and completely abolished H_2O_2-induced STAT activation. Within 5 min of V_2O_5 treatment, H_2O_2 was significantly decreased in the supernatants of cultured myofibroblasts and suppression of H_2O_2 levels continued for up to 24 h post V_2O_5 treatment. This supports the findings that myofibroblast-generated H_2O_2 is required for V_2O_5-induced STAT activation. **Temporal STAT-1 Activation:** H_2O_2 induced rapid activation within minutes whereas activation by V_2O_5 occurred more slowly (beginning 8h post treatment). **p38, ERK, EGFR:** p38 and EGFR are required for H_2O_2- or V_2O_5-induced STAT-1 activation whereas ERK is not required
Reference: Whitekus et al. (2002, 157142) **Species:** Mouse **Cell Line:** RAW 264.7	DEP (light-duty, four-cylinder engine-4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 50 µg/mL **Time to Analysis:** 5 h	DEP significantly reduced the GSH:GSSG ratio**.** This effect was prevented by adding thiol antioxidants NAC or BUC. DEP increased lipid peroxide levels, but the addition of all antioxidants decreased these levels. DEP increased carbonyl groups. NAC, BUC, and luteolin reduced HO-1 expression.

Study	Pollutant	Exposure	Effects
Reference: Wilson et al. (2007, 097268) **Species:** Mouse **Cell Type:** J774	CB: Carbon Black, Printex 90 (Degussa) $FeCl_3$ $ZnCl_2$ **Particle Size:** CB: 14 nm	**Route:** Cell Culture (4×10^5 cells/mL at 1mL/well) **Dose/Concentration:** CB 1.9 -31 µg/mL; $FeCl_3$, $ZnCl_2$ 0.01-100 µmol **Time to Analysis:** 4 h	**ROS Production in Cells:** CB alone increased ROS. Coexposure with $ZnCl_2$ did not affect ROS. **ROS Production - Cell Free:** CB induced a significant increase in ROS. $ZnCl_2$ had no effect. Coexposure CB/Zn also had no effect. **TNF-α Production (Fe -Zn 0.01-100 µmol):** Coexposure of CB over a range of metals gave no change over CB alone for Fe. For Zn, only at the concentration of 100 µmol was there a small interaction between Zn and CB. Similar results were seen at metal concentrations between 20 -100 µmol. Synergism was observed between Zn and CB and no observed effect of Fe. **Macrophage Cytoskeleton:** CB resulted in black vacuoles. Co-treatment of cells with Zn and CB increased the severity of Zn effects. Fe exhibited no synergism. **Apoptosis /Necrosis:** No synergism of CB with either Fe or Zn. **Phagocytosis:** Only at 31 µmol CB and 50 µmol Zn did a synergistic effect occur; it resulted in a 4-fold reduction.
Reference: Wottrich et al. (2004, 094518) **Species:** Human **Cell Type:** A549, THP-1, Mono Mac 6	Fe: hematite α-Fe_2O_3 Si60: silicasol (SiO_2, amorphous silica) Si100: silicasol Q: crystalline quartz DQ12 **Particle Size:** Fe: 50-90 nm; Si60: 60 nm; Si100: 80-110 nm; Q <5 µm	**Route:** Cell Culture (2×10^4 cells/well. Co-culture: 2×10^4 A549 and 2×10^3 Macrophages) **Dose/Concentration:** A549 light microscopy hematite 100µg/mL (23 µg/cm^2) TEM hematite 50 µg/mL (16 µg/cm^2) Cytotoxicity 10, 50, 100 and 200 µg/mL (6.1, 30, 61 and 121 µg/cm^2) Cytokines 50 and 200 µg/mL **Time to Analysis:** 24 h	**Particle Uptake:** Hematite agglomeration was observed in all 3 cell lines. TEM confirmed cytosol aggregates as well as single particles, which includes particles transported intracellularly to basolateral membrane of epithelial cells. **Cytotoxicity:** LDH increased significantly in A549. In decreasing order, Q , Fe, S60, and S100 (which exhibited levels similar to controls) all induced cytotoxicity. THP-1 cells appeared the most sensitive with Q, Fe, S60, S100, control inducing cytotoxicity in decreasing order. Mono Mac 6 cells were the least sensitive with Fe, S60, Q, S100. **Cytokines:** IL-6 and IL-8 released from A549 cells upon exposure to all particles. No response was observed in Mono Mac 6 or in THP-1 cells. **Co-cultures:** Mix of A549 with either Mono Mac 6 or THP-1 led to a large (ten fold) increase in response to particles. Ten fold increases were observed in IL-6 and IL-8 levels with the Mono Mac 6 co-culture and the THP-1 co-culture, respectively.

Study	Pollutant	Exposure	Effects
Reference: Wu et al. (2007, 098412) **Species:** Human **Cell Line:** B82L **Cell Type:** B82L- par (parental fibroblasts), B82L-wt (wild type EGFR), B82L-K721M (kinase defective EGFR), B82L-c'958 (COOH-terminally truncated EGFR at Tyr-958)	$ZnSO_4$ (Sigma) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Zn: 500 µmol EGF: 100 ng/mL **Time to Analysis:** 20 min	**EGFR Mutations:** EGFR-wt has a functional tyrosine kinase domain, intact Src phosphorylation (Tyr 845) and 5 tyrosine autophosphorylation sites. EGFR-c'958 lacks all 5 tyrosine autophosphorylation sites. EGFR-K721M lacks tyrosine kinase (ATP binding). EGFR-Y845F lacks Src autophosphorylation (Tyr 845) and, instead, has a receptor at Tyr 845 that is phosphorylated by nonreceptor Tyrosine kinase Src. **Zn Induced Ras (MAPK signaling protein):** No effect was observed in B82L-par cells. Zn had an effect in -wt, -c'958, and -K721M which confirms the need for EGFR. This indicates that neither tyrosine kinase nor autophosphorylation sites were required for Zn effects. No observed increase for Y845F indicated that EGFR tyrosine 845 (phosphorylated by c-Src) is required for Zn effects. However, it was not required for EGF effects. **Src Kinase Requirement:** Using a Src blocker drastically reduced Zn effect but not the EGF effect. Src activation occurred independent of EGFR Tyr-845. **Zn Induced Association of EGFR with Src:** Zn induced a physical association in all 4 mutants; EGF did not. **Zn Induced Phosphorylation of EGFR at Tyr-845:** Zn induced phosporylation of EGFR at Tyr-845 in B82L-wt,-c'958 and -K721M. EGF exhibited similar effects. Src blockers significantly reduced phosphorylation induced by Zn but not for EGF. Neither Zn or EGF induced phosphorylation in B82L-Y845F cells.
Reference: Wu et al. (2003, 199749) **Species:** Human **Cell Type:** BEAS-2B	Zinc Ion: Zn^{2+} **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 10, 25, 50 µmol **Time to Analysis:** 0-8 h	**Cytotoxicity:** Exposure to 50 µmol Zn^{2+} for 8 h did not result in significant alterations in cell viability. **PTEN Protein Levels:** 50 µmol Zn^{2+} for 4 and 8 h significantly decreased levels in a dose-dependent manner. Exposure to 50 µM vanadyl sulfate (tyrosine phosphatase inhibitor) had minimal effects on PTEN. 100 ng/mL of non-specified EGF receptor ligand for 1-8 h did not exhibit any significant effects on PTEN levels. **P13K/Akt:** Zinc induced Akt activation in a dose- and time- dependent fashion. Active Akt levels were the highest at 1 h post exposure to Zn^{2+}, corresponding with the time period when there was a minimal effect on PTEN protein level. When treated with LY294002 (inhibitor of P13K activity), Akt phosphorylation was significantly inhibited. **PTEN mRNA Levels:** Decreased PTEN mRNA expression was observed in cells exposed to 50 µmol Zn^{2+} for 8 h whereas PTEN protein levels declined as early as 4 h. **Proteasome-mediated PTEN Degradation:** Use of MG132 (proteasome inhibitor) had no significant effect on Zn^{2+} induced PTEN mRNA expression. Therefore mRNA expression may not play a critical role in PTEN protein reduction. Instead data suggested that 26 S proteasome played a vital role in Zn^{2+} induced PTEN degradation. PI3K inhibitor blocked Zn-induced PTEN degradation, but failed to prevent significant Zn-induced down-regulation of PTEN mRNA.

Study	Pollutant	Exposure	Effects
Reference: Wu et al. (2004, 096949) **Species:** Human **Cell Type:** NHBE	Zinc Ion: Zn^{2+} **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 100 µmol **Time to Analysis:** 2 h	**Cell Viability:** After 2 h of exposure, Zn^{2+} induced effects in NHBE cells at 100 and 200 µmol levels (but not 50 µmol). Continuing exposure to 100 µmol Zn^{2+} for 4 and 6 h did not significantly alter cell viability. Thus, in all subsequent studies, NHBE cells were treated with 100 µmol Zn^{2+}. **Induced EGFR Phosphorylation:** Exposure to 100µM Zn^{2+} for 1-4 h induced phosphorylation of EGFR in NHBE cells. EGFR kinase inhibitor PD153035 (to determine if phosphorylation of EGFR was the result of autophosphorylation of activated EGFR tyrosine kinase activity) caused Zn^{2+} -induced phosphorylation to subside. Zn^{2+} activity requires tyrosine kinase activity. **EGFR Phosphorylation Pathway:** To test whether Zn^{2+} exposure results in ligand release, which in turn can activate phosphorylation, NHBE cells were pretreated with LA1 blocking antibody. Results showed significant suppression of Zn^{2+} induced phosphorylation, therefore Zn^{2+} phosphorylation might be initiated by the release of EGFR ligands. **HB-EGF, TGF-α, EGF:** To examine the involvement of specific ligands (HB-EGF. TGF-α and EGF) in the phosphorylation pathway, cells were exposed to anti-HB-EGF, anti-TGF-α and anti-EGF. Results showed that anti-HB-EGF reduced Zn^{2+} induced phosphorylation significantly, anti-TGF-α produced partial inhibition and anti-EGF had no inhibitory effect. Exposure with blocking antibody LA1 was tested to determine if it caused an increase in soluble HB-EGF. HB-EGF mRNA expression was also elevated in cells exposed to Zn^{2+}. Previous studies indicate metalloproteinase (MMP) involvement in cleaving ligand precursors. It was found that MMP-3 inhibitor partially blocks Zn^{2+} induced HB-EGF release. (MMP-2 and MMP-9 did not show similar inhibition patterns) Zn^{2+} exposure increased the release of MMP-3 from HNBE cells.

Study	Pollutant	Exposure	Effects
Reference: Wu et al. (2005, 097350) **Species:** Human **Cell Line:** Subclone S6 **Cell Type:** BEAS-2B	Zinc Ion: Zn^{2+} **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 50 µmol **Time to Analysis:** 4 or 8 h; EGFR phosphorylation: 30, 60, 120, 240 min	**Cell Viability:** Exposure to 50 µmol Zn^{2+} for 8 h did not result in significant alterations in cell viability (assessed by LDH release). **P13K/Akt Signaling Pathway:** To evaluate P13K's on COX-2 Zn^{2+} induced expression, LY-294002 (a P13 inhibitor) and another unnamed P13 inhibitor were used. Exposed cells indicated suppressed levels of Zn^{2+} induced COX-2. To determine Akt role, ad-DN-Akt (AAA) was used. Infected cells indicated over-expression of Akt and significant reduction of Zn^{2+} induced GSK-3α/β phosphorylation. Over expression of DN-Akt(AAA) blocked Zn^{2+} induced COX-2 expression. **PTEN's Role in Blocking Zn2+ Induced COX-2 mRNA Expression:** PTEN is an antagonist of P13/Akt pathway. Overexpression of wildtype PTEN blocked Zn^{2+}-induced mRNA COX-2 expression, suggesting PTEN inhibits PIP3 signal transduction to Akt. **Analysis of the Src/EGFR Signaling Pathway:** Zn^{2+} induced a time-dependent increase in Src and EGFR phosphorylation in cells. Blockage of Src activity via PP2 (Src inhibitor) decreased Zn^{2+} induced EGFR phosphorylation. The EGFR tyrosine inhibitor completely blocked Zn^{2+}-induced EGFR phosphorylation. EGF (a ligand of EGFR signaling) induced COX-2 expression, suggesting that EGFR regulated Zn^{2+} -induced COX-2 expression. **p-38 and EGFR Kinase Activity:** Use of PD-153035 (EGFR inhibitor) and PP2 (Src inhibitor) and SB-203580 (p38 inhibitor) all blocked Zn^{2+}-induced Akt phosphorylation of Src., EGFR and p38. It is thought that p38 is a critical kinase in regulation of Zn^{2+} -induced COX-2 protein expression.
Reference: Yacobi et al. (2007, 156166) **Species:** Rat **Cell Type:** L2 (Lung epithelial cells)	PNP: Polystyrene nanoparticles, negatively charged (Molecular Probes, Eugene, OR) PNPA: Amidine modified PNP, positively charged SWCNT: Single-wall carbon nanotubes (Carbon Nanotech, Houston, TX) QDC: Chitosan coated (CdSe/ZnS) Quantum dots, positively charged (made) QDA: Alginate coated QD, negatively charged UAPS: Ultrafine Ambient particulate suspensions (VACES) (48 % OC) **Particle Size:** PNP20: 20 nm; PNP100: 100 µm; SWCNT: 0.8-1.2 nm (diameter); SWCNT: 100-1000 nm; QD: 30 nm; UAPS: <150 nm	**Route:** Cell Culture (1.2×10^6 cells/cm^2) **Dose/Concentration:** PNP up to 706 µg/mL QD up to 176 µg/mL SWCNT up to 88 µg/ mL UAPS up to 36 µg/mL **Time to Analysis:** on days 4, 5 or 6 by replacing monolayer apical fluid with PM in suspension for up to 1440 min. Intermediate measurements at 15, 30, 60, 120, 240 and 1440 min.	**UAPS and Rt (transmonolayer resistance):** Rt declined up to 60% within 1 h at 36 µg/mL. Rt plateaued (or exhibited a very slight upgradient) for up to 24 h (last measurement). No cytotoxicity was observed. Replacement of apical fluid with fresh media after 2 h of exposure restored Rt to near control values within 24 h. **UAPS and Leq (short-circuit current):** Peak decline of 30% after 4 h followed by gradual recovery over 24 h. Replacing media after 2 h exposure returned Ieq to control values within 24 h. **UAPS and Apparent Permeability:** Permeability measured via C14 mannitol and inulin showed no effect of UAPS. **QD and Rt:** QD depressed Rt by nearly 55% at 4 h for positively charged and 30% for negatively charged QDs. Recovery towards control values started at 4 h and was near complete at 24 h **SWCNT and Rt:** SWCNT depressed Rt by ~ 40% at 1 h (same for 22, 44, and 88 µg/mL). Recovery was near complete at 4 h and complete at 24 h. **PNP and Rt:** No statistically significant effects were observed.

Study	Pollutant	Exposure	Effects
Reference: Yun et al. (2005, 088302) **Species:** Human **Cell Type:** A549	DEP: Collected using a 6 cyl 11L, heavy duty (2001 yr) bus engine (South Korea) **Particle Size:** NR	**Route:** Cell Culture (3×10^4 cells/well) **Dose/Concentration:** 1, 10, 100, 250, 500 and 1000 µg/mL; main testing 250 µg/mL **Time to Analysis:** 12 h	**NF-κB Transcription Activation:** DEP induced dose-dependent activity up to 250 µg/mL. After peaking at 250 µg/mL, concentrations above 250 induced dose- dependent declines. Activity peaked at 12 h for 250 µg/mL and declined to control at 24 or 48 h. The mechanism of DEP action was the degradation of IκBα which is an intracellular inhibitor of nuclear translocation of NF-κB. **TAK1 and NIK Required for NF-κB Activation by DEP:** Dominant negative mutants of TAK1 and NIK reduced DEP induced response to basal level. TAK1 was phosphorylated after DEP exposure and was sustained for at least 90 min.
Reference: Zhang et al. (2007, 156179) **Species:** Human, Rat **Cell Type:** A549, RLE-6TN	$PM_{2.5}$: Collected by baghouse from Dusseldorf, Germany Particle Characterization: Carbon 20%, Hydrogen 1.4%, Nitrogen <0.5%, Oxygen 14.1%, Sulfur 2.1%, Ash 63.2%. **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** 100 µg/cm^2 **Time to Analysis:** 24 h	**Apoptosis:** At 100 µg/mL for 24 h, PM induced a 2.5 fold increase in apoptosis in A549. **Mitochondrial Membrane Potential:** A significant reduction in AEC mitochondrial membrane potential was observed. **Caspase -3 & -9:** Increased activity of both enzymes in both cell types was observed. More specifically, a 2- to 2.5-fold increase of caspase -3 and -9 in A549 and an 8-fold increase of caspase-9 and 4-fold increase of caspase-3 in RLE-6TN were observed. **BIM:** Downregulation of BIM by RNA interference inhibited PM-induced apoptosis. An inhibited decrease in mitochondrial membrane potential and activation of both caspases were observed.
Reference: Zhang et al. (2004, 157183) **Species:** Mice **Cell Line/Type:** C10 (alveolar Type II-like epithelial cell line)	DEP: SRM 1650a **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 5 or 25 µg/mL **Time to Analysis:** 30-360 min	**fra Expression:** DEP induces fra-1 but not fra-2 expression. mRNA induction peaks around 180 min DEP affects fra-1 mRNA expression at the transcriptional level. **ERK/JNK/p38 MAPK signaling pathways:** 3 inhibitors (PD-98059, SB-202190 or SP-600125) all reduced DEP stimulated fra-1 induction to near control levels. DEP stimulated phosphorylation of the MAPKs which peaks at 60 min but stays elevated at 180 min. **MMP-9 promoter activity:** fra-1 upregulation may play a role in DEP induced increases in MMP-9 promoter activity as fra-1 appears to bind at the -79 TRE sequence of the MMP-9 promoter.

Number of macrophages did not increase. **BAL Inflammatory/Injury Markers:** Total protein concentration significantly increased post 24 h inhalation. Post 4 h, heat shock proteins were induced. Post 24 h, immunomodulatory proteins (osteopontin, galectin-3 and lipocalin-2) significantly increased in alveolar macrophages and septal cells. 236 (1.9%) genes was increased and 307 (2.5%) genes were decreased with upregulated genes being primarily related to the inflammatory process.
Reference: Antonini et al. (2004, 097199) **Species:** Rats **Gender:** Male **Strain:** SD **Weight:** ~250 g	ROFA-P: Precipitator -S: Soluble (0.22 µm filter), Components: Fe, Al, Ni, Ca, Mg, Zn -I: insoluble, Components: Fe, Al, Ni, Ca, Mg, Zn, V -T: total ROFA-AH: Air Heater -S: Soluble (0.22 µm filter), Components: Fe, V, Ni, AL -I: Insoluble, Components: Fe, V, Ni, AL -T: Total **Particle Size:** < 3 µm (mean diameter)	**Route:** IT Instillation **Dose/Concentration:** 1mg/100g bw in 300 µl saline; 60 mg/kg **Time to Analysis:** 24 h; Clearance Experiment: two single exposures day 0 and 3 observed at day 6, 8 and 10	**ESR:** Only ROFA-P contained free radicals, primarily in ROFA-P-S. **BALF Cells:** No effects on alveolar macrophages were observed, but all ROFA-P fractions increased lung neutrophils. ROFA-P-S and ROFA-P-I effects combined roughly equaled ROFA-P-T. **BAL Inflammatory/Injury Markers:** ROFA-AH-T and ROFA-AH-I increased LDH. ROFA-P and -AH increased albumin for T and I fractions. **Pulmonary Clearance (Listeria Monocytogenes):** ROFA-P-T and ROFA-P-S significantly slowed bacteria clearance from lungs. ROFA-AH and ROFA-P-I had no effect.

Reference: Arimoto et al. (2007, 097973) **Species:** Mouse **Strain:** ICR **Gender:** Male **Age:** 6 wk **Weight:** 29-33 g	DEP (collected using a 4JB1 4-cyl, 2.74L Isuzu diesel engine) DEP-OC: organic chemical extracts LPS DL = DEP + LPS DOL = DEP-OC + LPS **Particle Size:** 0.4µm	**Route:** IT Instillation **Dose/Concentration:** DEP or DEP-OC: 4 mg/kg; LPS: 2.5 mg/kg; DL or DOL: NR **Time to Analysis:** 24 h	**Cytokines:** DEP-OC or DEP alone did not change levels of MIP-1α, MCP-1 or MIP-2. DL induced significant increases in MIP-1, MIP-2 and MCP-1. **LPS:** LPS and DOL induced increases in MCP-1 though the increase induced by DL was greater. No effect on MIP-1α or MIP-2 was observed.
Reference: Bachoual et al. (2007, 155667) **Species:** Mouse **Strain:** C5B17 **Gender:** Male **Age:** 7 wk **Weight:** 22.3 ± 073 g	RER: PM_{10} Paris, France subway CB TiO_2 DEP **Particle Size:** RER: 79% < 0.5 µm; 20%: 0.5-1 µm CB: 95 nm TiO_2: 150 µm DEP: NR	**Route:** IT Instillation **Dose/Concentration:** 5, 50, 100 µg/mouse, 0.22, 2.2, 4.5 mg/kg **Time to Analysis:** 8 or 24 h	**BALF Cells:** 100 µg RER and 100 µg DEP increased total cell count and neutrophil influx after 8 h and returned to normal by 24 h. Smaller doses of RER and DEP induced no effect. CB induced no effect. **BAL Inflammatory/Injury Markers:** 100 µg RER increased BALF protein after 8 h. No effect was observed after 24 h nor with smaller doses of PM. RER significantly increased MMP-12 mRNA level after 8 h and HO-1 total lung mRNA content. No effects on MMP-2 or -9 or TIMP-1 or -2 expression were observed. No effects from CB or DEP were observed. **Cytokines:** 100 µg RER increased BAL, TNF-α and MIP-2 protein content after 8 h.
Reference: Batalha et al. (2002, 088109) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** NR **Weight:** 200-250 g	CAPs (Harvard Ambient Particle Concentrator) **Particle Size:** Mean: 2.7 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** Range: 73.5-733 µg/m^3 **Time to Analysis:** CAPs exposure 5 h/day, 3 days (consecutive). SO_2 exposure to induce CB 5 h/day, 5 days/wk, 6 wk. Killed 24 h postexposure.	**Histopathology:** CAPs slightly increased the wall thickness of small pulmonary arteries and edema in the adventitia and hyperplasia of the terminal bronchiole and alveolar ducts epithelium. **L/W ratio:** The L/W ratio decreased in CAPs-exposed rats as particle mass, Si, Pb, SO42-, EC and OC increased. Univariate analyses showed significant negative correlations between the L/W ratio and Si and SO42- in normal rats and Si and OC in CB rats. Multivariate analysis showed only Si to be significant in both groups.
Reference: Becher et al. (2007, 097125) **Species:** Mouse **Strain:** Crl/Wky (iNOS(-/-)) and C57Bl/6 **Gender:** Male **Age:** 8-14 wk **Weight:** 25 g	Suspended PM: SRM-1648 **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 1.6 µg/lung; 64 mg/kg **Time to Analysis:** 20 h	**Cytokines:** In both wild and KO strains, all particles caused increases of IL-6, MIP-2 and TNF-α levels. NADPH-oxidase KO mice showed significantly lower levels of IL-6 and MIP-2 responses to SPM comparatively to wildtype. iNOS KO mice showed significantly reduced IL-6, TNF-α, MIP-2 responses to SPM comparatively to wildtype. **Free Radicals:** SPM induced significant increases in free radical formation in alveolar type 2 cells but could be inhibited by DPI.
Reference: Bhattacharyya et al. (2004, 088095) **Species:** Mouse **Strain:** SD **Weight:** 200-250 g	Douglas Fir Wood Smoke (generated by burning wood at 400˚C in crucible oven) **Particle Size:** NR	**Route:** Nose-only Inhalation **Dose/Concentration:** 25 g/mouse **Time to Analysis:** Various exposure periods (0, 5, 1 0, 15, 20 min). Parameters measured after 24 h recovery period.	**Biochemical Parameters:** Lipid peroxidation increased after 20 min of wood smoke inhalation as did Myeloperoxidase at 20 min. No effects were observed at other times or for total antioxidant status, reduced or oxidized glutathione. **Antioxidant Enzyme Activities:** No effect was observed. **Histology:** Dose-dependent damage progressing from loss of cilia (5 min), degeneration of mucosal epithelium, loss of mucosal epithelium to disrupted mucosal epithelium with submucosal edema and inflammation. Changes persisted for up to 4 days.

Reference: Cao et al. (2007, 097491) **Species:** Rat **Strain:** SH and WKY **Age:** 12 wk	$PM_{2.5}$ (Shanghai, China) Components: As, Cd, Cr, Cu, Fe, Ni, Pb, Zn, V, Ba, Se, Mg, Co, Mn **Particle Size:** $PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** 1.6, 8.0 and 40 mg/kg **Time to Analysis:** Exposed 1/day for 3 days, sacrificed 24 h following last exposure	**BALF Cells:** PM decreased macrophages and increased neutrophils and lymphocytes in a dose-dependent manner. For the same exposed dose, WKY rats had a higher percentage than SH but a smaller percentage of neutrophils and lymphocytes. **BAL Inflammatory/Injury Markers:** LDH activity and TBARs increased a in dose-dependent manner. Notably, activity in SH rats was much higher than WKY at the same dose exposed for each dose level. **Cytokines:** PM induced pro-inflammatory cytokine release (IL-1β, TNF-α, CD44, MIP-2, TLR-4, OPN). Again, SH cytokine level was greater than WKY at all dose levels. PM induced anti-inflammatory cytokines CC16 and HO-1 in a similar manner but at much lower rate.
Reference: Carter et al. (2006, 095936) **Species:** Rat, Mouse, Hamster **Gender:** Female (all) **Strain:** F-344 (rat), B6C3F1 (mouse), Syrian Golden (hamster) **Age:** 7-10 wk	CB: Printex 90 **Particle Size:** primary size: 17 nm; 1.2-1.6 µm (aerosol aerodynamic diameter)	**Route:** Whole-body Inhalation **Dose/Concentration:** 1, 7, 50 mg/m^3 **Time to Analysis:** 6 h/day for 5 days/wk for 13 wk; 1 day, 3 m, 11 m post-exposure	**Superoxide:** Levels rose in all species at 50 mg dose. Hamsters had no increase at 7 and 1 mg doses. Mice also increased at 7 mg. Rats significantly increased at all dose levels. Rats maintained elevation except for the 50 mg dose at 11 mo postexposure; it declined but was still higher than control. Mice maintained elevation at 50 mg while 7 mg returned to control levels by 3 mo postexposure. **H_2O_2:** At 50 mg, increased levels in all species, with the highest in rat, were observed. At 7 mg, increased levels in rats and mice were initially seen but levels returned to baseline by 11 mo. Hamster levels were not significant. At 1 mg, no significant changes were observed. **NO:** Induced similar reactions as H_2O_2. Rat response continued through the study while mice and hamsters returned to baseline by 11 mo postexposure. Rats produced significantly higher levels at all times than other species. **BALF Cells:** CB induced significant increases in neutrophils at 7 and 50 mg for all species. Rats had the highest and most prolonged PMN response. Mice and hamsters had very similar reactions. **Cytokines:** TNF-α, MIP-2 and IL-10 increased in a dose-dependent manner in rats and mice. Hamsters increased for IL-10 only. MIP-2 levels were highest in rats. TNF-α level were similar in all three species at 50 mg, but hamsters started with a markedly higher basal level. **Glutathione Peroxidase:** Hamsters were the most responsive with significant increases at all levels. Rats and mice increased at 50mg and continued to increase for up to 11mo. Hamster levels declined with time but continued to be higher than control. **Glutathione Reductase:** Rats increased only at 50mg and remained elevated for up to 11mo. Mice increased at 7 and 50mg and remained elevated for up to 11mo. Hamsters increased at all levels at 11mo, but at 50mg, levels only increased post 1 day. **Superoxide Dismutase:** All species reacted in a dose-dependent manner. Rats were the least responsive. Rat SOD activity increased over time while rat and mouse activity decreased at 50mg. Data were consistent with cytokine data. **Summary:** Rats appear to produce proinflammatory responses while mice and hamsters produce antiinflammatory responses.

Reference: Cassee et al. (2005, 087962) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto and SH/NHsd **Age:** 7 wk and 8-12 wk	CAPs: $PM_{2.5}$ Netherland suburban, industrial and freeway tunnel site collections Wistar rats pre-exposed to O_3 SO_4, NO_3 and NH_4 ions: 54 ± 4% suburban, 53 ± 7% industrial and 35 ± 5% freeway site conc. of total CAPS mass **Particle Size:** $PM_{2.5}$ (0.15<PM<2.5 µm)	**Route:** Nose-only Inhalation **Dose/Concentration:** PM 365-3720 µg/m^3 (results from 16 different exposures 2000, 2002); O_3: 1600 µg/m^3 (0.8 ppm) **Time to Analysis:** 8 h O_3 pre-exposure; 6 h CAPS exposure; 48 h post-exposure	**BALF Cells:** Wistar exhibited increased protein, albumin, NAG and decreased ALP activity and macrophage numbers. Wistar showed increased PMNs due to O_3, but was not significantly increased with additional CAPs exposure. SH showed no effect of CAPS except for the increased PMNs. **BAL Inflammatory/Injury Markers:** No effect on AL, LDH, Glutathione, GSSG, GSH, Uric Acid was observed. **Cytokines:** No effect on IL-6, MIP-2 or TNF-α was observed. CAPs induced an increase in CC16 plasma of SH rats. **Hematology:** CAPS induced an increase in RBC, HGB and HCT of Wistar rats and fibrinogen of SH rats. **Histology:** Wistar and SH rats had no obvious lung abnormalities. Small changes include increased macrophages and cellularity of centriacinar septa of O_3-only rats. Both O_3-only and O_3+CAPS showed bronchial epithelium hypertrophy and perivascular influx of PMNs. **BrdU Labeling Index of Terminal Bronchiolar Epithelium:** No CAPs effects were observed.
Reference: Chang et al. (2005, 097776) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 5 wk **Weight:** 25-30 g	UFCB: Ultrafine Carbon Black - Printex 90 (Degussa) **Particle Size:** 14 nm	**Route:** IT Instillation **Dose/Concentration:** 200 µg/100 uµ/mouse **Time to Analysis:** Parameters measured 4, 16, 21, 42 h post single exposure	**BALF Cells:** Neutrophil number was at control level at 4 h, increased after 16 h, peaked at 21 h and returned to normal at 42 h. No effect was observed for the macrophage count. **BAL Inflammatory/Injury Markers:** UfCB increased total protein with peak at 21 h. TNF-α increased at 4 h and returned to normal at 16 h. **VEGF (Vascular Endothelial Growth Factor):** Increased at 4 h and peaked at 16 h but remained elevated at 21 and 42 h. VEGF and total protein in BALF were correlated (R_2 = 0.7352). **ROS:** Pretreatment with NAC (ROS inhibitor) decreased induction of BALF VEGF and total protein by UfCB but did not fully block its effect. **Histology:** Thickened alveolar walls in lungs of UfCB-treated mice 16 h post-IT was observed.
Reference: Chang et al. (2007, 097475) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 5 wk **Weight:** 25-30 g	UFCB: Ultrafine Carbon Black - Printex 90 (Degussa) **Particle Size:** 14 nm diameter	**Route:** IT Instillation **Dose/Concentration:** 200 µg/mouse; 8 mg/kg **Time to Analysis:** Pretreatment with NAC (N-acetylcysteine) ip 320 mg/kg, 2 h before UFCB IT instillation. Parameters measured 24 h post exposure.	**BALF Cells:** Increased relative lung weight, total protein (2 fold), total cells (11 fold) and number of neutrophils were observed. BALF AM count was not affected. **BAL Inflammatory/Injury Markers:** Of the 33 identified proteins, the following 6 were confirmed and validated: Cp (ceruluplasmin), albumin, EGFR, LIFR (leukemia inhibitory factor receptor), α2M and β-actin. All were increased following UFCB exposure. The following were also identified: 3 membrane proteins, 3 intracellular proteins, 10 protease inhibitors and 6 antioxidants. UfCB increased LIFR and EGFR in BALF. UfCB significantly reduced EGFR and LIFR in lung homegenate. UfCB did not affect EGFR protein but down-regulated LIFR in A549 cells treated with UfCB. **Antioxidant:** Pretreatment with NAC reduced the intensity of albumin and α2M bands in BALF as well as most other proteins. Statistical analysis showed positive correlation between VEGF and albumin (R_2 = 0.796) and VEGF and α2M (R_2 = 0.7331) in BAL.

Reference: Cho et al. (2005, 156344) **Species:** Mouse **Gender:** Male **Strains:** DBA/2J, 129P3/J, C57BL/6J, BALB/cJ, A/J, C3H/HeJ, C3H/HeOuJ **Age:** 6-8 wk	ROFA: Obtained from Power unit 4, Boston, MA Absent of LPS **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 6 mg/kg bw (150 µg in 50µl/ 25 g) **Time to Analysis:** 24 h; Additional HeJ and OuJ mice: single: 1.5, 3 and 6 h (compare TLR-mediated molecular events)	**BALF Cells:** Significant genetic effects on number of macrophages and PMNs after ROFA challenge. For PMNs, DBA/2J, C57BL/6J, BALB/cJ, and 129P3/J all induced increases significantly higher than C3H/HeJ. For macrophages, only the A/J strain induced increases significantly higher than C57BL/6J. Total protein, PMNs and macrophages all increased with HeOuJ inducing increases significantly different from HeJ. **BAL Inflammatory/Injury Markers:** Significant genetic effect on mean total protein concentration was observed. In decreasing order, DBA/2J, 129P3/J and C57BL/6J all induced increases significantly higher than C3H/HeJ. **TLR4 mRNA Expression:** A significant decrease was observed in TLR4 transcript level in HeJ- ROFA exposed mice post 1.5 h. Post 6 h, TLR4 levels were greater than the control levels. OuJ expression increased beginning 1.5 h post exposure. **TLR4 Protein Level:** Protein level of OuJ mice significantly exceeded (~2-3 fold) HeJ mice at 1.5, 3 and 6 h. **Activation of Downstream Signal Molecules:** Greater activation of MYD88, TRAF6, IRAK-1, NF-KB, MAPK, and AP-1 was observed in OuJ mice than in HeJ mice before the development of ROFA- induced pulmonary injury. **Cytokines:** IL-1β, LT-β, IL-1α, IL-7, IL-13, IL-16 increased in both strains (OuJ and HeJ). Levels of all cytokines above were significantly higher in OuJ than in HeJ.

Autopsy Tissue. **Dose/Concentration:** 10 - >1000×10^6 g dry tissue; Mexico City: PM_{10}: 66 µg/m^3, Vancouver: PM_{10}: 25 µg, $PM_{2.5}$: 15 µg **Time to Analysis:** Lung samples taken from deceased lifelong Mexico City residents and Vancouver residents >20 yr. Subjects were never-smokers, did not work in dust occupations or cook with biomass fuels.	The lungs from Mexico City residents showed increased muscle and fibrous tissue in the membranous bronchioles and respiratory bronchioles compared to the Vancouver residents. Pigmented dust, lumental distortion and carbonaceous aggregates of UFPs were present in the Mexico City lungs.
Reference: Costa et al. (2006, 088438) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 60 day	ROFA FP&L plant #6 oil, 1% sulfur **Particle Size:** ~1.95 µm	**Route:** IT Instillation, Nose-only Inhalation (IH) **Dose/Concentration:** IT instillation = 110 µg/rat IH = 12 mg/m^3 **Time to Analysis:** IT instillation: single; IH: 6 h 24, 48, 96 h (histopathology 24 and 48 only)	**ROFA distribution:** IH and IT instillation resulted in equivocal distribution (µg/g lung tissue) in 5 different lung lobes. **Airway Hyperactivity:** IT instillation resulted in doubled airway hyperreactivity at 24 h which was sustained for 96 h. IH hyperreactivity did not reach statistically significant level. **BALF Cells:** Neutrophils peaked at 24 h and slowly declined at 48 and 96 h. **BAL Inflammatory/Injury Markers:** IH and IT instillation showed very similar responses (R_2 = 0.98). Time-dependent increases were observed for protein and LDH. **Lung Pathology:** IT instillation showed more alveolitis, bronchial inflammatory and fibrinous fluid infiltrate. IH showed relatively more congestion of small airways and alveolar hemorrhage.

Reference: Dick et al. (2003, 036605) **Species:** Mouse **Gender:** Female **Strain:** CD1 **Age:** 8-10 wk **Weight:** 20-25 g	CO: PM Coarse FI: PM Fine FU: PM ultrafine PM collected in RTP, NC **Particle Size:** CO: 3.5-20 µm; FI: 1.7- 3.5 µm; FU: <1.7 µm	**Route:** IT Instillation **Dose/Concentration:** 10 µg, 50 µg, 100 µg/mouse; 0.5, 2.5, 5.0 mg/kg **Time to Analysis:** DMTU 500 mg/kg bw 30 min pre-exposure for some mice. Parameters measured 18 h post-exposure.	**Particle Characteristics:** S increased (CO-33.20 µg/mg, FI- 49.44 µg/mg FU- 122.79 µg/mg) with decreasing particle size (mostly in the water-soluble fraction). Fe and Cu higher in coarse and fine fractions (mostly present in the insoluble). CO PM contained more nickel (in both soluble and insoluble) than FI or FU particles. Also, endotoxin levels similar in CO and FI; much lower in FU (0.165 EU/mg). **BALF Cells:** PMN increased with exposure for all 3 fractions except 100 µg FI. **BAL Inflammatory/Injury Markers:** Albumin increased only at 100 µg FI. No differences in NAG or LDH observed. **Cytokines:** IL-6 increased at 100 µg dose for all 3 fractions with similar responses. TNF-α increased a 100 µg dose of fine PM vs control. **Effect of PM After Pre-treatment w/DMTU:** Systemic administration of DMTU alone depicted a two-fold increase in total antioxidant capacity. **DMTU halved neutrophil response observed with PMs alone:** No fractions were increased over DMTU alone which was at least two-fold saline control. IL-6 concentrations were drastically reduced in the DMTU group for the mice exposed to coarse particles (all fractions were reduced but only coarse had a significant response). TNF-α levels were decreased after treatment with particles and DMTU but treatment with particles and saline (control) produced similar results.
Reference: Dybdahl et al. (2004, 089013) **Species:** Mouse **Gender:** Female **Strain:** BALB/CJ or trans-genic (MutaMouse) **Age:** 9-10 wk **Weight:** ~20 g	DEP: SRM 1650 (NIST) **Particle Size:** DEP: NR; Control: PM 0.13 µm diameter	**Route:** Nose-only Inhalation **Dose/Concentration:** I: 20, 80 mg/m^3 II: 5, 20 mg/m^3 **Time to Analysis:** I: single exposure 90 min; II: 90 min/day for 4 days; I & II: parameters measured 1, 3, or 22 h post exposure	**Cytokines:** A single 90 min DEP exposure increased IL-6 gene level dose-dependently in the lung. For 80 mg/m^3 DEP, significantly higher IL-6 gene level was observed, both 1 and 22 h post exposure. For 20 mg/m^3 DEP, a significantly higher IL-6 level was observed at 1 h post exposure but normalized at 3 h. **BALF Cells:** Inhalation of DEP did not decrease viability of BALF cells. For mice exposed to 20 mg/m^3 DEP, at 1 h post exposure in BAL fluid there was 3 fold increase in total cell number. **DNA Damage:** Level of 8-oxodG increased post single exposure with 80 mg/m^3 inducing levels significantly higher than controls. Repeated exposures were associated with significantly higher DNA strand breaks.
Reference: Elder et al. (2004, 055642) **Species:** Rat **Gender:** Male **Strain:** F344, SH **Age:** 23 m (Fisher), 11-14 m (SH)	UFP: argon-filled chamber with electric arc discharge (TSI, Inc., St. Paul, MN) **Particle Size:** 36 nm	**Route:** Whole-body Inhalation. **Dose/Concentration:** UFP: 150 µg/m^3 bw; LPS: 2 mg/kg **Time to Analysis:** 6 h, 18 h	**BALF Cells:** Neither inhaled UFP nor LPS cause a significant increase in BALF total cells or percentage of neutrophils in either rat strain. No significant exposure-related alteration in total protein concentration was observed. In both rat strains LPS induced a significant increase in the amount of circulating PMNs. When combined with inhaled UFP, PMNs decreased; for F-344 rats, this decrease was significant. **ROS in BALF:** In F-344 rats, both UFP and LPS have independent and significant effects on DCFD oxidation. Effects were in opposite directions; particles decreased ROS whereas LPS increased ROS.

Reference: Elder et al. (2004, 087354) **Species:** Rat **Gender:** Male **Strain:** F344 **Age:** 21 mo	Freshly generated vehicle exhaust emissions from I-90 between Rochester and Buffalo, NY **Particle Size:** NR	**Route:** Whole-body Inhalation; IT Instillation (Influenza) **Dose/Concentration:** Vehicle exhaust: 0.95-3.13×10^5 particles/cm^3 Endotoxin: 84 EU Influenza (IV): 10, 000 EID 50 in 250 µl **Time to Analysis:** 1×6 h, 3×6 h or both. Parameters measured 18 h post-exposure. 48 h prior to on-road exposures, instilled intratracheally with IV. Immediate pre-exposure of priming agent endotoxin. EXPERIMENTS 1: LPS + PM 6 h 2: LPS + PM 6 h, 3×6 h 3: IV + PM 6 h 4: IV + PM 6 h, 3×6 h	No departures from normal baseline cellular or biochemical values were observed, suggesting that on-road exposures were well tolerated by the rats. **BAL Inflammatory/Injury Markers:** Increase in total protein concentration, LDH and B-glucuronidase activities were observed. **Specific results according to groups 1-4 are as follows:** **Experiment 1:** No endpoints revealed significant differences between groups of rats exposed to gas phase only versus the gas-phase/particle mixture. **Experiment 2:** Combination of endotoxin and particles produced greater inflammatory responses than those treated with saline and particles post 1 day. After 3 days, no statistically significant changes were noted. **Experiment 3:** Influenza virus significantly increased ROS release in BALF cells. **Experiment 4:** Influenza virus significantly increased both percentage of PMNs in BALF and BALF cell ROS release.
Reference: Elder et al. (2005, 088194) **Species:** Rat, Mouse, Syrian Golden Hamster **Gender:** Female **Strain:** F-344, B6C3F1, FIB	HSCb: Printex-90 high surface area carbon black, Deguss-Huels (Trostberg, Germany). LSCb: Sterling V, low surface area carbon black, Cabot (Boston, MA) **Particle Size:** HSCb = 14 nm, LSCb = 70 nm	**Reference:** Whole-body Inhalation **Dose/Concentration:** 0, 1, 7, 50 mg/m^3 HSCb; 50 mg/m^3 LSCb (rats only) **Time to Analysis:** 6 h/day, 5 daus/wk for 13 wk. Parameters measured 1 day, 3 mo, 11 mo post-exposure	**Body Weight:** Environmental changes pre and post-exposure affected test subjects' life spans, particularly hamsters. Hamsters also experienced significant loss of body weight when exposed to high doses of HSCb. **Effects of Carbon Black:** In rats, lung weight of the high dose HSCb doubled. After 11mo, analysis of all lungs showed no significant difference. Mice had the highest relative lung burdens at the end of exposure time but also cleared particles faster at high doses than rats. However, clearance slowed over the 11mo recovery period, especially in high dose mice. Hamsters showed significant elevations in lung carbon black burden for all exposures at all time points. Hamsters exposed to high dose HSCb exhibited impaired clearance. **BALF Cells:** Presence of PMNs was limited to the mid and high dose groups. Overall maximal response was reached in mice and hamsters, but not in rats with increasing mass dose of HSCb.
Reference: Evans et al. (2006, 097066) **Species:** Rat **Gender:** Male **Strain:** SD	DEP: collected under dry, outdoor, ambient conditions from tractor exhaust pipe (1985, Japanese ISEKI 1500 cc tractor) burning Esso 2000 diesel and 20/30 mixture of Esso light engine oil. 10% UF, 90% fine Cabosil: amorphous silicon dioxide 16% UF, 84% fine **Particle Size:** DEP: 30 nm; Cabosil: 7 nm	**Route:** IT Instillation **Dose/Concentration:** 1 mg/rat DEP; 1 mg/rat Cabosil **Time to Analysis:** Pretreatment with 0.5 unit of bleomycin; IT 3 or 7 days after pre-treatment; 1wk post-IT	**Lung permeability:** In bleomycin-treated group, obvious inflammatory status and edema within the lung was observed. This was shown by significant increases in acellular protein and free cells. **Changes in lung:** Body weight ratio, lung surface protein content, free cell counts, and apical surface protein of rat type I cells were only altered by bleomycin treatment and not particle exposure.

Reference: Finnerty et al. (2007, 156434) **Species:** Mouse **Gender:** Male **Strain:** C57BL/61 **Age:** 12 wk **Weight:** 24.3 ± 0.3 g	Coal Fly Ash (generated at U.S EPA National Risk Management Research Laboratory by burning Montana subbituminous coal under conditions simulating full-scale utility boiler conditions) Transition metals of Coal Fly Ash: Fe, Mg, Ti, Mn, V **Particle Size:** >$PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** PM: 200 mg/mouse; 9.1 mg/kg PM+LPS10: 200 mg PM+10 mg LPS PM+LPS100: 200 mg PM+100 mg LPS LPS: 100 µg **Time to Analysis:** 18 h	**BALF Cells:** No significant differences in platelet concentration or white blood cell count in any groups were observed. The percentage of neutrophils increased significantly with PM+LPS100. PMN rose in PM groups and increased further with LPS treatment. Increases in PM+LPS were groups statistically significant. More leukocytes were present in the alveolar space in PM+LPS10 compared to the PM group. The most severe response was in the PM+LPS100 group. **Cytokines:** Plasma TNF-α and IL-6 significantly increased for the PM+LPS100 group. An additive effect of LPS and PM for IL-6 was observed. For saline and PM groups, pulmonary TNF-α was below detection range. A synergistic effect for TNF-α was observed. A less than additive effect for IL-6 was observed. Pulmonary TNF-α significantly increased in the PM+LPS100 group. Pulmonary IL-6 significantly increased in both PM+LPS groups.
Reference: Fujimaki et al. (2006, 096601) **Species:** Mouse **Gender:** Male **Strain:** IL-6(-/-) and WT: B6J129Sv (control) **Age:** 5-6 wk	DEP: collected from a 4-cylinder, 2.74 L, Isuzu diesel engine **Particle Size:** 0.4 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 1.0, 3.0 mg/m^3 **Time to Analysis:** 12 h/dayfor 4 wk. Parameters measured 1 day post-exposure	**BALF Cells:** Treatment significantly increased BAL cells from WT mice at both dose levels. The increase of macrophages and neutrophils were dose-dependent. An increase in lymphocytes were present in WT mice with the low dose. No significant increase in cells were observed from IL-6 (-/-). **Cytokines:** TNF-α largely increased in IL-6(-/-) mice exposed to 3 mg/m^3 compared to WT mice. IL-6 production increased in WT mice exposed to 3 mg/m^3. CCL3 increased in both WT and IL-6(-/-) at high dose. IL-1β remained at the control level.
Reference: Gerlofs-Nijland et al. (2005, 088652) **Species:** Rat **Gender:** Male **Strain:** SH/NHsd **Age:** 11-12 wk **Weight:** 250-350 g	RTD: road tunnel dust (obtained from a Motorway tunnel in Hendrik-Ido-Ambacht, Netherlands) EHC-93 (Ottawa, Canada) **Particle Size:** Coarse: 2.5- 10 µm; fine: 0.1- 2.5 µm	**Route:** IT Instillation **Dose/Concentration:** 0.3, 1, 3, 10 mg/kg; EHC-93: 10 mg/kg **Time to Analysis:** 4, 24, 48 h	**BALF Cells:** PMN significantly increased in RTD (3 and 10 mg/kg dose) and EHC-93 exposed animals at 24 h and decreased by 48 h but remained statistically significant. AM numbers decreased for 3 mg/kg RTD group at 4 h. **BAL Inflammatory/Injury Markers:** Myeloperoxidase (measured at 24 h in 1, 3, 10 mg/kg RTD groups) was elevated in a dose-dependent manner. RTD induced time-dependent increases in LDH activity at 24 and 48 h, although these increases were less than EHC-93 values at the same time points. Alkaline phosphatase increased dose-dependently for RTD at 48 h. GSH decreased at 24 h to approximately the same levels in 0.3, 1, and 3 mg/kg RTD dose groups. Uric acid only decreased in 1 mg/kg RTD group at 24 h. **Cytokines:** IL-6 levels were elevated only at 10 mg/kg for RTD and EHC-93 at 4 and 24 h; it remained elevated for EHC-93 at 48 h. A dose-dependent increase in TNF-α at 4 h for RTD was observed. TNF-α levels remained elevated only for the 10 mg/kg groups at 24 h and returned to control levels by 48 h. A dose-dependent increase in MIP-2 for all RTD dose groups were observed and remained elevated through 48 h for both PM types (although values were returning to control levels). **Pulmonary Histopathology:** A dose-dependent increase in the number of inflammatory foci at 24 and 48 h for 3 and 10 mg/kg RTD groups was observed. The response was even greater for the EHC-93 exposed group at similar time points.

Reference: Gerlofs-Nijland et al. (2007, 097840) **Species:** Rat **Gender:** Male **Strain:** SH/NHsd **Age:** 13 wk **Weight:** 250-350 g	PM samples collected from: 1. MOB high traffic density 2. HIA high traffic density 3. ROM high traffic density 4. DOR moderate traffic density 5 MGH low traffic density 6 LYC low traffic density **Particle Size:** Coarse: 2.5 - 10 µm; Fine: 0.1 - 2.5 µm	**Route:** IT Instillation **Dose/Concentration:** 3, 10 mg/kg **Time to Analysis:** 24 h	**BALF Cells:** Pulmonary inflammation was induced in a significant and dose-dependent manner for both dose levels. Inflammation in the BALF included airway neutrophilia, increased macrophage numbers and mild lymphocytosis. Both coarse and fine PM caused dose-dependent alveolitis. Fine PM from LYC (10 mg/kg dose) also caused some bronchiolitis. **BAL Inflammatory/Injury Markers:** LDH was significantly increased for all doses of coarse PM and for the high dose of fine PM. BALF protein concentration was observed predominantly at the high dose of coarse PM. Location ROM had evidence of attenuated responses with fine PM. Ascorbate concentrations were reduced but were only significant for rats exposed to the highest dose of coarse PM fractions from the locations MOD, HIA, and LYC. **Cytokines:** TNF-α concentrations increased for all coarse samples with the exception of DOR and LYC. Fine PM induced similar responses for all sites. MIIP-2 concentrations increased only at certain sites for coarse but not fine PM. **Location-related Differences:** Coarse PM from MOB, HIA and MGH induced higher LDH responses than other locations. Coarse PM from HIA produced BALF protein concentrations higher than LYC and ROM. MGH induced greater amounts of BALF protein than ROM. Coarse PM from LYC lowered fibrinogen values more than PM from location MOB, HIA, and MGH. Fine PM showed less differences among the various sites. **Particle Correlation:** Fine PM exhibited significant correlation between zinc content and BALF cytotoxicity markers protein and LDH - mainly from HIA. Fine PM also exhibited positive correlations with copper and barium. Coarse PM showed positive correlation with barium and copper, mainly from MOB.
Reference: Gerlofs-Nijland et al. (2009, 190353) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 12 wk **Weight:** 200-300 g	PM (Prague, Czech Republic; Duisburg, Germany; Barcelona, Spain) (Prague and Barcelona coarse PM organic extracts) **Particle Size:** Coarse: 2.5-10 µm, Fine: 0.2-2.5 µm	**Route:** IT Instillation **Dose/Concentration:** 7mg/kg **Time to Analysis:** 24 h	Cytotoxicity (LDH, protein, albumin) and inflammation (NAG, MPO, TNF-α were increased by PM, and were greatest in the coarse PM fraction. Metal-rich PM had greater inflammatory and cytotoxic effects. PAH content influenced greater inflammation (including neutrophils), and cytotoxicity. Generally, whole PM and coarse PM were more potent than organic extracts and fine PM, respectively.
Reference: Ghio et al. (2005, 088272) **Species:** Rat **Gender:** Male **Strain:** N8 b/b Belgrade rats and N8+ Ib Belgrade controls	Oil Fly Ash (Southern Research Institute, Birmingham, AL) **Particle Size:** 1.95 ± 0.18 µm (MMAD)	**Route:** IT Instillation **Dose/Concentration:** 500 µg/rat; 2 mg/kg **Time to Analysis:** 24 h	**BALF Cells:** Homozygous Belgrade with mutation G185R had higher levels of Fe and V 24 h post-exposure. This may demonstrate a decreased ability to remove Fe and V from the lower respiratory tract than heterozygous +Ib littermates. This also indicates that DMT1 is normally responsible for at least some Fe and V uptake; thus, a defective DMT1 transports less. **BAL Inflammatory/Injury Markers:** Increased protein and LDH concentrations in the homozygous strain were observed when compared to control
Reference: Ghio et al. (2005, 088275) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 60 day **Weight:** 250-300 g	Ferric ammonium citrate (FAC) Vanadyl sulfate ($VOSO_4$) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 0.5 mL 100 µm FAC/rat; 0.5 mL 10 µm $VOSO_4$/rat; 500 µg oil fly ash; 2 mg/kg **Time to Analysis:** Single or double exposure with 24 h rest period. Parameters measured 15, 30, 60 min, 24 h post-exposure.	**DMT1 Immunohistochemistry and Lung Injury:** FAC increased and $VOSO_4$ decreased -IRE DMT1 staining. Same exposures had no effect on +IRE DMT1. -IRE DMT1 expression in macrophages, airway and alveolar epithelial cells increased with increased Fe exposure. Vanadium nearly eliminated staining except in alveolar macrophages. Increased metal clearance with pre-exposure to FAC. Less metal clearance with pre-exposure to $VOSO_4$. Pre-exposure to iron diminished lung injury whereas pre-exposure to vandium increased lung injury after oil fly ash instillation. Lung injury measured by concentration of protein and LDH in BAL.

Reference	Pollutant	Exposure	Effects
Reference: Gilmour et al. (2007, 096433) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 10-12 wk **Weight:** 20-22 g	PM - CO, FI, UF (obtained from U.S. Seattle (S), Salt Lake City (SL), South Bronx (SB), Sterling Forest (SF)) SB: included 35% sulfate, 22% gasoline, diesel and brake wear. SF: 48% sulfate. SL: 34% wood combustion and 28% sulfate S: 39% wood combustion and 29% sulfate Residual oil combustion and soil dust less than 5% for all sites. **Particle Size:** CO: 2.5-10 µm; FI: ≤ 2.5 µm; UF: ≤ 0.1 µm	**Route:** Oropharyngeal Aspiration **Dose/Concentration:** 25 µg or 100 µg PM; 1.25 or 5 mg/kg **Time to Analysis:** 18 h	**BALF Cells:** PMN increased with the high dose of CO samples from SB, SL, S, but not SF. No significant increases from FI were observed, though the high dose induced increased PMN. UF from SL caused a highly variable response. **BAL Inflammatory/Injury Markers:** Seattle CO fractions showed no dose-dependent effect on protein concentration. Results for other locations were distinctly higher with 100 µg dose than 25 µg and saline doses. SL CO high dose induced the most significant increase. LDH response was weakly dose-related. Only SB showed a statistically significant increase for LDH with the high dose UF. **Cytokines:** MIP-2 was similar to PMN response. SB CO induced the most significant response. SL UF was highly variable. **Particle Characteristics:** LPS was higher in S (CO, FI, UF) and SL (CO, FI, UF). Zn levels were highest in SB (CO, FI, UF). Fe was higher in all CO and FI samples with SB CO inducing the highest.
Reference: Gilmour et al. (2004, 057420) **Species:** Mouse **Gender:** Female **Strain:** CD1 **Age:** 8-10 wk **Weight:** 20-25 g	Coal Fly Ash MU: Montana Ultrafine MF: Montana Fine MC: Montana Coarse KF: W. Kentucky Fine KC: W. Kentucky Coarse Particle Characteristics: Montana Sulfur 0.83%, Ash 11.72%. Trace amounts of Ba, P, Sr, V, Nb, Cd, Se, Ga, Cu. Depleted in Si, Al, Fe, Mg, Ti. Kentucky Sulfur 3.11%, Ash 8.07% **Particle Size:** Coarse: >2.5 µm; Fine: <2.5 µm; Ultrafine: <0.2 µm	**Route:** Oropharyngeal Aspiration **Dose/Concentration:** 25 ug or 100 µg/mouse **Time to Analysis:** 18 h	**BALF Cells:** PMN highly increased for MU at both doses. The level was comparable to the positive control. PMN also increased with KF at high dose. Coarse particles caused no significant increase in PMN. Number of macrophages did not change, but NAG increased significantly with MU for both dose levels and with KF and MF at high dose level. **BAL Inflammatory/Injury Markers:** Total protein and LDH was not significantly elevated. Albumin concentration increased significantly after treatment with the fine high dose of both particle types. **Cytokines:** MU particles caused a significant increase in TNF-α. MIP-2 increased in all fine and ultrafine PM-instilled animals with the highest in the MU and KF at both doses. IL-6 was detectable only in the BALF of MU and KF with substantial variability. The IL-6 levels were not significant.
Reference: Gilmour et al. (2004, 087948) **Species:** Rat **Gender:** Male **Strain:** SH/NQIBR, WKY **Age:** 12 wk **Weight:** 280-340 g	PM (collected from precipitator unit of an oil burning power plant in Boston) Measured Components of PM: S, Zn, Ni, V, Al, Cu, Pb, Fe, Ca, Na, K, Mg, Endotoxin **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 0.0, 0.83, 3.3, and 8.3 mg/kg in SH rats; 0.0 or 3.3 mg/kg in WKY and SH rats **Time to Analysis:** 24 h	**BALF Cells:** No increase in macrophage number was observed in either rat strain following saline or PM exposure at 24 h. **BAL Inflammatory/Injury Markers:** LDH activity increased in a dose-related manner; this was observed in SH rats after exposure to 0.83, 3.33 and 8.3 mg/kg PM. SH rats showed greater lung permeability following PM exposure than WKY rats. SH rats showed acute lung inflammatory response after exposure to PM when compared to WKY rats. **Cytokines:** MIP-2 mRNA expression increased significantly in SH PM exposure group only. No significant differences in TNF-α RNA expression in either WKY, SH rats or control treatment groups were observed. **CD14:** A significant increase in lung CD14 protein was observed only in SH rats exposed to PM. **TLR4:** A significant increase in TLR4 protein in SH rats exposed to PM was observed. **NF-κB:** A significant increase in NF-κB binding protein in the nuclei of SH rats exposed to PM was observed. This effect was not observed in the control of PM-exposed WKY rats.

Haeffner and Co) **Particle Size:** ufCB: 14 nm; CB: 260 nm (primary particle diameter)	**Route:** Whole-body Inhalation **Dose/Concentration:** ufCB: 1.66 mg/m^3 fCB: 1.40 mg/m^3 Number concentrations ufCB: 52380 particles/cm^3 fCB: 3800 particles/cm^3 **Time to Analysis:** Exposed for 7 h. Sacrificed 0, 16 or 48 h post-exposure.	**BALF Cells:** Total number of cells increased significantly in UfCB-exposed rats at 0 and 16 h. Recruitment of cells did not occur in response to CB exposure. PMNs increased significantly in the BALF of ufCB-exposed rats at 16 h. Leukocytes remained unchanged following CB exposure but increased significantly at 0 and 48 h post exposure to ufCB. **Cytokine mRNA:** A significant increase in BALF MIP-2 mRNA expression was observed at 48 h. No differences in MIP-2 mRNA levels were observed in the whole lung tissue.
Reference: Godleski et al. (2002, 156478) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** NR **Weight:** 200-250 g	CAPs (Boston; Harvard Ambient Particle Concentrator) **Particle Size:** 0.27 ± 2.3 µm (diameter)	**Route:** Whole-body Inhalation **Dose/Concentration:** 73.5-733 µg/m^3 **Time to Analysis:** Exposed 5 h/days, 3 days (consecutive). BAL 24 h post-exposure	**BALF Cells and Inflammatory Markers:** PMNs significantly increased with CAPs exposure and also in relation to CAPs mass, Br, SO_4^{2-}, EC, OC and Pb. An overall increase in pro-inflammatory mediators and decrease in immune enhancer and evidence of vascular endothelial responses occurred with CAPs exposure.
Reference: Gottipolu et al. (2009, 190360) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto, SH **Age:** 14-16 wk **Weight:** NR	DE (30-kW (40hp) 4-cylinder indirect injection Deutz diesel engine) (O_2- 20%, CO- 1.3-4.8 ppm, NO- <2.5-5.9 ppm, NO_2- <0.25-1.2 ppm, SO_2- 0.2-0.3 ppm, OC/EC- 0.3 ± 0.03) **Particle Size:** Number Median Diameter: Low- 83 ± 2 nm, High- 88.2 nm; Volume Median Diameter: Low- 207 ± 2 nm, High- 225 ± 2 nm	**Route:** Inhalation **Dose/Concentration:** Low- 507 ± 4 µg/m^3, High- 2201 ± 14 µg/m^3 **Time to Analysis:** Exposed 4 h/day, 5 days/wk, 4 wk. Necropsied 1 day post-exposure.	DE increased neutrophils in a concentration-dependent manner, and GGT activity at the high dose. Particle-laden macrophages were found in DE-exposed rats.
Reference: Gunnison and Chen (2005, 087956) **Species:** Mouse **Gender:** Male **Strain:** DK (ApoE$^{-/-}$, LDLr$^{-/-}$) **Age:** 18-20 wk	CAPS (Northeastern regional background) Ambient air copollutants measured O_3, NO_2 **Particle Size:** 389 ± 2 nm	**Route:** Whole-body Inhalation **Dose/Concentration:** CAPS = 131 ± 99 µg/m^3 including O_3 = 10 ppb and NO_2 = 4.4 ppb **Time to Analysis:** 6 h/day, 5 days/wk for 4 mo (5/12/03-9/5/03). Sacrificed 3-4 days post-exposure.	**Microarray Data:** 13 genes in the heart tissue and 47 genes in the lung tissue were identified as possibly affected. Strict standards (1.5 fold response, 10% false discovery rate) resulted in responses by only 1/13 genes (Rex3 - no known heart physiology) in the heart tissue and 0/47 genes in the lung tissue. Using more liberal response (nonstatistical) standards (1.5 fold only) and comparison of each CAPS animal with all 3 control animals (3x3 array) resulted in possible effects on 7 additional genes in the heart tissue and 37 genes in the lung tissue.
Reference: Gurgueira et al. (2002, 036535) **Species:** Rat **Gender:** Male **Strain:** SD **Weight:** 250-300 g	CAPs (Harvard Ambient Particle Concentrator) CB (C198 Fischer Scientific, Pittsburg, PA USA) Composed of 85.9 ± 0.2% Carbon, 13.0 ± 0.2% O_2, 1.17 ± 0.2% Sulfur ROFA (Boston, MA USA oil-fired power plant) **Particle Size:** CAPs: 1-2.5 µm; CB: <2.5 µm; ROFA: <2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 300 ± 60 µg/m^3 **Time to Analysis:** 1, 3, 5 h CAPs Exposure followed by immediate post-exposure analysis. 5 h CB, immediate analysis. 30min ROFA, Immediate analysis.	**In situ Chemiluminescence(CL):** Data show a significant increase in lung and heart CL at 5 h. Lung CL increased linearly with time of exposure. **Oxidants:** CAPs-initiated oxidative stress was not detectable in those rats allowed to recover in room air after the simulated "peak" in particulate air pollution. Rats breathing particle-free filtered air for 3 days had significantly lower levels of oxidants. Exposure to inert CB did not exert oxidant effects on the heart and lung. **BAL Inflammatory/Injury Markers:** The water content of the lung and heart increased significantly upon exposure to CAPs but not to filtered air and increased as a function of length of exposure. Rats breathing CAPs also showed increases in LDH and CPK as a function of length of exposure. **Antioxidant Enzymes:** Data showed an increase in SOD and catalase activities in both the lung and heart. The pattern of increase was tissue specific.

Reference: Hamoir et al. (2003, 096664) **Species:** Rabbit **Strain:** New Zealand **Age:** 12-16 wk **Weight:** 2.8 ± 0.5kg	PSC: Polystyrene particles, Carboxylate modified, 3 types PSA: Polystyrene particles, Amine modified, 1 type **Particle Size:** PSC: 24, 110 or 190 nm (PSC24, PSC110, PSC190); PSA: 190 nm	**Route:** IT Instillation **Dose/Concentration:** PSC24: 0.04 or 4 mg/rabbit PSC110, PSC190, PSA190: 4 mg/rabbit **Time to Analysis:** 0, 30, 60, 90, 120 min	**Capillary Filtration Coefficient:** A time-dependent increase correlating to total number of particles/surface area, not particle size, was observed. PSA induced a significant increase in microvascular permeability as compared to PSC. This suggests that the number of particles exposed should be considered an important parameter for measuring air quality rather than total particle surface area.
Reference: Happo et al. (2007, 096630) **Species:** Mouse **Gender:** Male **Strain:** C57BL/6J **Weight:** 19-30 g **Age:** 10-11 wk	PMC (Coarse) PMF (Fine) PMUF (Ultrafine) Collected in 6 European cities: Duisburg, Prague, Amsterdam, Helsinki, Barcelona, Athens **Particle Size:** PMC: PM_{10}-2.5; PMF: $PM_{2.5}$-0.2; PMUF: PM0.2	**Route:** IT Instillation **Dose/Concentration:** 1, 3, 10 mg/kg Time course: 10 mg/kg **Time to Analysis:** 1. Dose-Response study: parameters measured 24 h post exposure. 2. Time course study: parameters measured 4, 12, 24 h post single exposure (at 10 mg/kg).	**BALF Cells:** 1. For the dose-response study, all the PMC samples exhibited dose-dependent increases of total cell numbers. The 3 and 10 mg/kg doses of PMC induced statistically significant increases. At 10 mg/kg, only 2/6 samples induced statistically significant increases. No PMUF samples induced effects at any dose. 2. For the time-response study, no increases in cell numbers were shown at 4 h. Though the levels induced by PMC at 24 h were lower than at 12 h, both levels were statistically significant. PMF induced statistically significant increases only at 12 h for 4/6 samples. PMUF induced only 1 significant increase at 12 h; the 24 h time point was not tested. **BAL Injury Markers:** 1. The lower doses of 1 and 3 mg/kg did not induce significant increases in any of the PM samples, except for PMUF-Athens. All 6 samples of PMC, at 10 mg/kg, induced significant increases. At 10 mg/kg, 4/6 PMF samples induced significant increases. 2. At 4 h, none of the samples increased protein concentration. The PMC samples, excluding Prague, induced significantly higher concentrations at 12 h. At 24 h, only 3/6 PMC samples induced significant increases. Only 2 PMF samples induced significant increases at 12 and 24 h. At 12 h, effects induced by PMUF were minimal and inconsistent; the 24 h time point was not tested. **Cytokines:** 1. Only PMC induced dose-dependent responses that reached statistical significance at 10 mg/kg. PMF and PMUF induced minimal and inconsistent responses. 2. TNF-α levels increased significantly at 4 and 12 h by PMC. At 24 h, TNF-α levels returned to near control levels. PMF, at 4 h, induced statistically significant increases for 3/6 samples and significant increases in 2/6 samples at 12 h. No PMUF samples significantly increased TNF-α levels. PMC induced the highest IL-6 levels at 4 h. Levels at 12 and 24 h were reduced with 6/6 and 3/6 samples showing statistically significant increases, respectively. PMF showed a similar trend with 4 h inducing the highest levels that were reduced at 12 and 24 h. Of the PMUF samples, only the Helsinki and Duisburg samples induced statistically significant results at 4 and 12 h. Generally, the PMUF responses were negligible when compared to PMC and PMF. 2. All PMC samples induced the highest levels of KC production at 4 h. At 12 and 24 h, levels were reduced but 4/6 samples induced statistically significant levels. PMF showed a similar trend- the highest levels were induced at 4 h (in 3/6 samples). PMUF at 4 h showed small, though not significant, increases. At 12 h, only 2 samples showed statistically significant differences from the control; the 24 h time point was not tested.
Reference: Harder et al. (2005, 087371) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 14-17 wk **Weight:** NR	Carbon UFP **Particle Size:** 37.6 ± 0.7 nm (diameter)	**Route:** Inhalation **Dose/Concentration:** 180 µg/m^3 **Time to Analysis:** 24 h exposure. 3 day recovery.	UFP induced mild pulmonary inflammation, significantly increased PMN, and increased the total protein and albumin concentrations. Particle-laden macrophages sporadically accumulated in the alveolar region.

Reference: Harkema et al. (2004, 056842) **Species:** Rat **Gender:** Male **Strain:** F344, BN **Age:** 10-12 wk **Weight:** NR	CAPs (Detroit; July-Sept. 2000; Harvard Ambient Fine Particle Concentrator) **Particle Size:** 2.5 µm (diameter)	**Route:** Inhalation, IT Instillation. **Dose/Concentration:** 4 day concentration: 676 ± 288 µg/m^3, 5 day concentration: 313 ± 119 µg/m^3, July concentration: 16-185 µg/m^3, September concentration: 81-755 µg/m^3; IT Instillation- 200 µL (soluble and insoluble) **Time to Analysis:** F344 rats sensitized to endotoxin, BN rats to OVA. Exposed 10 h/day 1, 4, 5 days (consecutive). Another group of rats IT instilled. Both groups killed 24 h post-exposure.	The retention of PM in the airways was enhanced by allergic sensitization. Recovery of anthropogenic trace elements was greatest for CAPs-exposed rats. Temporal increases in these elements were associated with eosinophil influx, BALF protein content and increased airway mucosubstances. A mild pulmonary neutrophilic inflammation was observed in rats instilled with the insoluble fraction but instillation of total, soluble or insoluble $PM_{2.5}$ in allergic rats did not result in differential effects.
Reference: Hiramatsu et al. (2003, 155846) **Species:** Mouse **Gender:** Female **Strain:** BALB/c and C57BL/6 **Age:** 8 wk **Weight:** 17-22 g	DE: generated by 2369-cc diesel engine (Isuzu) at 1050 rpm and 80% load with commercial light oil **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** DEP: 100 µg/m^3 or 3 mg/m^3; SO_2<0.01 ppm; NO_2 2.2 ± 0.3 or 15 ± 1.5 ppm; CO 3.5 ± 0.1 or 9.5 ± 0.6 ppm **Time to Analysis:** 7h/d, 5 days/wk for 4 or 12 wk, Immediate	**BALF Cells:** Alveolar macrophages (AMs) increased dose-dependently at 30 and 90 day. High DE exposure resulted in bronchus-associated lymphoid tissue (BALT) around DEP-AMs; this was less conspicuous in C57BL/6 than in BALB/c mice. B- and T-cell populations were found in the BALT with no significant differences observed between the strains. Lymphocytes and neutrophils increased time- and dose-dependently with a greater increase in BALB/c than C57BL/6 observed. No eosinophils or basophils were observed. Mac-1-positive cells exposed to high DE levels increased in both strains at 1 month (33.8%) and 3 mo (20.3%) vs. low dose group (5.3 and 7% respectively). **Cytokines:** At 30 days, TNF-α, IL-12p40, IL-4 and IL-10 mRNA increased, IL1b and iNOS decreased. IFN-γ increased in BALB/c but decreased in C57BL/c. IL-6 mRNA was not affected. At 90 day, IL-4 and IL-10 mRNA similarly increased in C57BL/6 mice exposed to low DE level but decreased at high DE level.

Total number of neutrophils with lavage fluid increased 24 h post-exposure in both strains.
Reference: Hutchison et al. (2005, 097750) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 3 m **Weight:** 250-300 g	PM_{10} United Kingdom samples collected before (-B), during closure (-C) and reopening of steel plant (-R) PMT = PM total (aqueous sonicate) PMS = PM aqueous supernatant PMI = PM insoluble pellet **Particle Size:** PM_{10}	**Route:** IT Instillation **Dose/Concentration:** 112 to 180 µg PM in 500 µl; 0.44-0.72 mg/kg **Time to Analysis:** 18 h	**BALF Cells:** PMT-R neutrophil cell number and percentage were significantly higher than PMT-C or control. PMS-R and PMI-R were also higher than their respective controls. The neutrophil cell numbers induced by PMI-R were greater than PMI-C and the control. Total cell count unchanged. **BALF Inflammatory/Injury Markers:** Only albumin increased after PMT-R. Upon exposure, total protein and LDH did not increase. **Cytokine mRNA expression:** Only PMT-R increased IL-1ß mRNA expression. No effects on TNF-α and TGF-ß expression levels were observed. IL-6, MIP2, and GM-CSF mRNA was not detected in BAL cell extracts from either the control or treated groups.
Reference: Inoue et al. (2006, 097815) **Species:** Mouse **Gender:** Male **Strains:** C3H/HeJ (TLR-4 point mutant) and C3H/HeN (Control) **Age:** 6 wk	DEP (derived from 4 cyl, 2.74l light duty diesel engine) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 12 mg/kg **Time to Analysis:** 24 h	**BALF Cells:** DEP induced an increase in total cells, neutrophils, and mononuclear cells. TLR4 knockout mice (C3H/HeJ) showed a much lower response. **Cytokines:** DEP induced a massive increase in MIP-1x, IL-1β and KC. However, levels of MIP-1x were significantly less in the knockout than the wild type while levels of IL-1β and KC were significantly higher in knockouts than the wild type.

Reference: Inoue et al. (2005, 097481) **Species:** Mouse **Gender:** Male **Strain:** NC/Nga **Age:** 10 wk	DEP (derived from 4 cyl, 2.74l light duty diesel) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 100 µg/mouse **Time to Analysis:** 1/wk for 6 wk. Parameters measured 24 h after last administration	**BALF Cells:** DEP significantly increased total cells, neutrophils and mononuclear cells but did not induce an effect on eosinophils. **Cytokines:** DEP increased IL-4, KC and MIP-1. The increase in IL-5 was not statistically significant.
Reference: Ishihara et al. (2003, 096404) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 5 wk	DE (from 2 engines, produced on site) -L = low level DE -M = medium level -MG = DE w/o particulates -HR = high level Measured Components: NO_2, SO_4, SO_2, CO, CO_2, NO_X, NO, HTHC, HCHO, O_2 **Particle Size:** L: 0.33 -0.50 µm M: 0.35 - 0.40 µm HR: 0.42 - 0.45 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** L: 0.18 - 0.21 mg/m^3 M: 0.92- 1.18 mg/m^3 MG: 0.01 mg/m^3 HR: 2.57 - 2.94 mg/m^3 **Time to Analysis:** 16 h/day, 6 days/wk, for 6, 12, 18 & 24 mo. Parameters measured immediately following last exposure.	**Morbidity and Mortality:** Weight gain in HR group was less than other groups at 18 and 24 mo. This indicates a significant difference between the HR and C group. Mortality during the study was frequent. C group experienced an 8% mortality rate, L group 12%, M group 15%, MG group 12% and HR group 23%. **BALF Cells:** The HR group showed a significant increase in total cell count from 6 to 18 mo. The percentage of PMN increased at 6mo in M, MG and HR group. M group lymphocytes significantly increased at 6, 12, and 24 mo of exposure. Macrophages decreased at 6 mo for the M and HR groups. **BAL Inflammatory/Injury Markers:** Significant differences were seen among groups with respect to number of total cells and percentages of cell differential, total protein, fucose, sialic acid, phospholipid and prostoglandin E2. Total protein increase was observed in both M and HR dose groups with the HR group increasing time-dependently. **Mucus and Surfactant:** The HR group showed a significant increase from 12 to 18 mo.
Reference: Jones et al. (2005, 198883) **Species:** Rabbit **Strain:** New Zealand **Weight:** 2.5- 3.5 kg	ASP: Amorphous silica particles (Hypersil) MCSP: Microcrystalline silica particles **Particle Size:** ASP: 5 µm; MCSP: 5 µm	**Route:** Intrapulmonary Instillation (Right upper lobe of lung) **Dose/Concentration:** 50mg in 0.5 mL saline **Time to Analysis:** Parameters measured at varying times from 6 h to 91 days post treatment.	**MCSP:** At 6 h, neutrophils increased. Macrophages increased 3 fold. At 60 h, neutrophils were pyknotic and the lungs displayed a thickened interstitium containing silica particles. At 5 days, collagen deposition appeared. At 8 days, fibroblastic activity and necrosis were observed. At 15 days, aggregation of silica particles and necrotic debris were apparent. At 8 wk, fibroblasts were still present. At 13 wk, active scarring and raised neutrophil macrophage counts were still present. **ASP:** At 15 h, neutrophils increased. Macrophages tripled and remained increased for 3wk. At 4 day, macrophages bore particles. At 13 day, neutrophils decreased significantly. By 25 day, silica spheres were gradually removed from lungs. **PET Scanning:** 18F-fluoroproline showed increased activity beginning at 14 days and peaking at 41-54 days. **Microautoradiography:** 3 h-proline at 13 wk showed radiolabel localization to fibroblasts in the challenged lung.

Reference: Kato and Kagawa (2003, 089563) **Species:** Rat **Gender:** Male **Strain:** Jcl Wistar **Age:** 5 wk	Roadside air (Prefectural Tokyo-Danishi-Yokohama highway, Yokohama-Haneda Airport Metropolitan expressway and Satsukibashi-Mizuecho city road, Japan) **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** Exposed group: 62.7 µg/m^3 PM, 55.7 ppb NO_2,; Control group: 14.3 µg/m^3 PM, 5.1 ppb NO_2 **Time to Analysis:** Exposed for 24, 48, 60 wk. Parameters measured immediately following exposure.	**Respiratory Tissue:** Post 24 wk, the lung surface was light gray with some BC particle deposits. Post 48-60 wk, however, the surface was scattered with particle deposits in addition to its light gray color. **Airway Changes:** After 60 wk, no remarkable changes seen in the epithelium. The structure of the airways remained normal. **Cells:** No proliferation or ectopic growth of goblet cells were noted. Mast cells increased in epithelial intercellular space. No mast cell degranulation was observed. Lysosomes increased in ciliated cells post 48 wk. Clara cells were unaffected. **Lymph Nodes:** Deposition of carbon particles were noted in the trachea and bronchiole-associated lymph nodes post 24 wk. **Alveolar Changes:** No changes in morphology of broncho-alveolar junctions were noted. Anthracosis observed within alveolar walls and pleura post 24 wk and became progressively marked with increased exposure. No change in the number of alveolar holes between exposure and control groups were observed.
Reference: Kato et al. (2003, 198882) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 7 wk **Weight:** 190-220 g	Polystyrene latex suspension of latex beads (Japan Synthetic Rubber Co.), uncoated or coated with lecithin **Particle Size:** 240 nm	**Route:** IT Instillation with nebulizer **Dose/Concentration:** 5 ml of 0.2% suspension administered over 20 min at flow rate of 0.25 ml/min **Time to Analysis:** Exposed for 20 min. Parameters measured 30 min following treatment.	**Alveolar Macrophages:** Following treatment, AMs appeared undamaged. AMs ingested more uncoated than coated beads, but both were ingested. Ingestion of beads differed as coated beads were engulfed individually while uncoated beads were engulfed individually or in aggregates. **Epithelial Cells:** Type I cells incorporated coated beads within a layer of cytoplasm. Type II cells incorporated beads in lamellar bodies. Uncoated beads were not incorporated. **Other:** Neither type of beads were incorporated into endothelial cells, fibroblasts or interstitium of alveolar wall **Monocytes:** Only the coated beads were incorporated by the monocytes. They were found inside and outside phagosomes and lysosomes of monocytes. PMNs did not incorporate any beads.
Reference: Kleinman et al. (2003, 053535) **Species:** Rat **Gender:** NR **Strain:** F344n-NIA **Age:** 22-24 m	O_3 CCL: O_3 + Ammonium bisulfate (ABS) + Elemental Carbon (EC) CCH: O_3 + ABS + EC Purified Air (control) **Particle Size:** CCL: 0.30 ± 2.5 µm; CCH: 0.29 ± 2.3 µm	**Route:** Nose-only Inhalation **Dose/Concentration:** O_3: 0.2 ppm CCL: 50 µg/m^3 EC + 70 µg/m^3 ABS + 0.2 ppm O_3 CCH: 100 µg/m^3 EC + 140 µg/m^3 ABS + 0.2 ppm O_3 **Time to Analysis:** 4 h/days, 3 consecutive days/wk for 4 wk	**BALF Cells:** CCL and CCH induced macrophage respiratory burst activity. The effect induced by O_3 was not significant. **BAL Inflammatory/Injury Markers:** Total protein, mucus glycoprotein and albumin were somewhat elevated in all exposure groups but only reached statistically significance for CCL and protein (very high variability). CCL and CCH both depressed Fc receptor side binding. No effect for O_3 was observed. **DNA Replication:** O_3 caused a slight effect of 20-40% increase. CCL and CCH caused between 250 - 340% increase for interstitial and epithelial cells. CCL induced greater reactions than the high dose.
Reference: Kleinman and Phalen (2006, 088596) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 6 wk **Weight:** 200 g	LO_3: Low O_3 HO_3: High O_3 LS: Low H_2SO_4 HS: High H_2SO_4 LOLS: Low O_3 + Low H_2SO_4 LOHS: Low O_3 + High H_2SO_4 HOLS: High O_3 + low H_2SO_4 HOHS: High O_3 + high H_2SO_4 **Particle Size:** LS = 0.23 µm ± 2.3 HS = 0.28 µm ± 2.1 LOLS = 0.23 µm ± 2.3 LOHS = 0.28 µm ± 2.1 HOLS = 0.23 µm ± 2.3 HOHS = 0.28 µm ± 2.1	**Route:** Nose-only Inhalation **Dose/Concentration:** LO_3 = 0.30 ppm HO_3 = 0.61 ppm LS = 0.48 mg/m^3 HS = 1.00 mg/m^3 LOLS = 0.31 ppm + 0.41 mg/m^3 LOHS = 0.31 ppm +1.04 mg/m^3 HOLS = 0.60 ppm + 0.52 mg/m^3 HOHS = 0.60 ppm + 0.86 mg/m^3 **Time to Analysis:** Exposed for 4 h. Parameters measured 42 h post-exposure.	**Inflammatory Lesions in Lung Parenchyma:** Neither Type 1 or 2 lung lesions were affected by sulfuric acid alone. HO_3 doubled Type 1 lesions and increased Type 2 lesions 25-fold. Additions of H_2SO_4 to O_3 appeared to have a dose-dependent protective effect for both types of lesions. **DNA Synthesis in Nasal, Tracheal and Lung Tissue:** Increased DNA synthesis was observed at all high O_3 exposures but was not affected by coexposure to H_2SO_4. **Macrophage FcR binding:** No effects were observed (no data for LO_3 and HO_3). **Macrophage Phagocytosis:** All levels of exposure (no data for LO_3 and HO_3) decreased phagocytosis.

Reference: Kodavanti et al. (2005, 087946) **Species:** Rat **Gender:** Male **Strain:** WKY and SH/NCrlBR **Age:** 11-14 wk	CAPs (EPA, NC) Measured components included Al, Be, Ba, Co, Cu, Zn, Pb, Mn, Ni, Ag, Ti, As. **Particle Size:** 1 day: 1.07-1.19 µm; 2 days: 1.27-1.48 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 1 day study: 1138-1765 µg/m^3 2 day study: 144-2758 µg/m^3 **Time to Analysis:** 4 hr (SH only); 4 hr/day, 2 day (WKY and SH) Post-exposure: 1 day: 3 h except study #4, 18-20 h; 2 day: 18-20 h	**Breathing Parameters:** In a paired analysis of control SH and treated SH, treated SH showed an increase in expiratory and inspiratory time due to CAPs. The treated and control groups of WKY rats did not show significant differences. **BALF Cells:** In the 2 day study, WKY rats showed decreases in total cells; this decrease was associated with decreased macrophages. WKY showed an increase in neutrophils. **BAL Inflammatory/Injury Markers:** Total protein and albumin in WKY rats decreased whereas SH rats maintained the same approximate level. LDH activity lowered slightly in both strains. **Cell Membrane Integrity:** SH rats showed increased GGT (membrane bound enzyme) activity and plasma fibrinogen for 5/7 exposures but these increases did not appear to be dose-dependent. **Cytokines:** Levels were undetermined in SH rats. WKY showed slight increases in IL-6, TNF-α, and MIP-2 but these increases were not statistically significant.

(2006, 097547) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 12-14 wk	CAP-F = fine (Site I) CAP-UF = fine + ultrafine (Site II) (Netherlands) Some measured components: Ammonium, nitrate, sulfate ions: 56 ± 16% CAP-F mass, 17 ± 6% CAP-UF mass **Particle Size:** 0.15<CAP-F<2.5 0.65-0.75 µm CAP-UF<2.5 0.58-1.41 µm	**Route:** Nose-only Inhalation **Dose/Concentration:** CAP-F 399- 3613 µg/m^3 CAP-UF 269-556 µg/m^3 **Time to Analysis:** 6 h/day for 2 days consecutive, 18 h	**BALF Cells:** A decrease in absolute neutrophils as well as percentages of reticulocytes and percentages of neutrophils were observed with CAP-F. Increased percentages of lymphocytes were observed with CAP-F. **BALF Inflammatory/Injury Markers:** Based on unchanged levels of LDH and ALP, no cytotoxicity was noted. No significant change in the levels of total cells were observed. MDA (malondialdehyde) decreased with CAP-UF. Ho-1 increased with CAP-UF and CAP-F. **Cytokines:** CC16 decreased at 457µg/m^3 of CAP-F and increased at 3613 µg/m^3 of CAP-F. **Pathology.** No changes were observed.
Reference: Kumar et al. (2004, 096655) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Weight:** 150 ± 20 g	Fly Ash (Obra Thermal power Station, India) **Particle Size:** PM <5 µm (90%)	**Route:** Whole-body Inhalation **Dose/Concentration:** 14.4 ± 1.77 mg/m^3 (fluid bed generator) **Time to Analysis:** 4 h/day for 28 day. Parameters measured immediately following last exposure.	**Lung Weight:** Lung body weight increased 25.58% relative to controls. Total body weight slightly decreased in the treated group. **BALF Cells:** Only eosinophils(%) increased 95% over controls. Congestion and focal infiltration of monocytes in alveolar area was seen. Fly ash laden macrophages in alveoli combined with hypertrophy of epithelial lining cells was observed. **BAL Inflammatory/Injury Markers:** LDH, GGT, ALP and lavagable protein increased by 140, 450, 160 and 50%, respectively.
Reference: Lei et al. (2004, 087999) **Species:** Rat **Gender:** Male **Strain:** SD **Weight:** 318 ± 8 g	CAPs (Yaipei, Taiwan) **Particle Size:** 0.01- 2.5 µm	**Reference:** Nose-only Inhalation **Dose/Concentration:** 371 ± 208 µg/m^3 **Time to Analysis:** 6 h/day for 3 day, 5 h post-exposure pulmonary function. 2 day post-exposure for BALF collection Pulmonary hypertension induced 2 wk pre-exposure	**Respiratory Effects:** Decreased respiratory frequency and increased tidal volume for both experimental and control groups were observed. However, only the experimental group levels were statistically significant. There was an increase in airway responsiveness (Penh/methacholine) for CAPs group when compared to the control. **BALF Cells:** A massive increase in total cell number and percent neutrophils was observed. There were no changes in percent macrophages, lymphocytes and eosinophils. **BAL Inflammatory/Injury Markers:** Total protein and LDH increased in the CAPs group. **Cytokines:** TNF-α and IL-6 were not affected.

Sacrificed 36 h post-exposure High: Exposed for 4.5 h. Sacrificed 36 h post-exposure Pulmonary hypertension induced 2 wk pre-exposure.	**BALF Cells:** PM induced dose-dependent increases in total cells and percentage of neutrophils. No change in macrophages, lymphocytes or eosinophils occurred. Basophils were highly variable. **BALF Inflammatory/Injury Markers:** Dose-dependent increases were observed for total protein and LDH. **Cytokines:** IL-6 increased dose-dependently. (control: 33.5 ± 7.5, low 165.1 ± 117.2, 273.6 ± 62.8 pg/mL).
Reference: Li et al. (2007, 155929) **Species:** Mouse **Gender:** Female **Strain:** BALB/c, C57BL/6 **Age:** 9 wk **Weight:** NR	DEP (2369-cc diesel engine manufactured by Isuzu Motor, operated at 1050 rpm, 80% load, commercial light oil) **Particle Size:** NR	**Route:** Inhalation **Dose/Concentration:** DEP: 103.1 ± 9.2 µg/m^3, CO: 3.5 ± 0.1 ppm, NO_2: 2.2 ± 0.3 ppm, SO_2: <0.01 ppm **Time to Analysis:** Protocol 1: Exposed 7h/day, 5 days/wk. Sacrificed at day 0, week 1, 4, 8. Protocol 2: DE alone or DE+NAC 7h/day, 1-5 days.	**Airway Hyperresponsiveness:** Penh values increased in BALB/c mice compared to the control at day 0, but no significant changes occurred after this time. Penh values increased in C57BL/6 mice at 1 wk compared to the control but returned to control levels at 8 wk. **BALF:** Compared to the other strain, the total number of cells and macrophages increased significantly at 1 wk in C57BL/6 mice and at 8 wk in BALB/c mice. Neutrophils, lymphocytes, MCP-1, IL-12, IL-10, IL-4, IL-13 increased significantly for both strains. No eosinophils were found. IL-1β and IFN-γ increased significantly in BALB/c mice compared to C57BL/6 mice. **HO-1 mRNA and Protein:** HO-1 mRNA was more marked in BALB/c mice at 1 wk and C57BL/6 mice at 4 and 8 wk. HO-1 protein percentage changes from the control were greater in BALB/c mice at 1 wk and C57BL/c mice at 8 wk. **NAC:** NAC inhibited the increased Penh values, total number of cells and macrophages in C57BL/6 mice at 1 wk and neutrophils and lymphocytes in both strains.

Reference: Mangum et al. (2004, 097326) **Species:** Rat **Gender:** Female **Strain:** CDF (F344)/CrlBR **Age:** 7 wk	TiO_2 (DuPont) **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** 10, 50 or 250 mg/m^3 **Time to Analysis:** 6 h/day, 5 days/wk, 13 wk. Parameters measured 0, 4, 13, 26, 52 wk post-exposure.	**OPN (osteopontin) Expression:** At 0 wk, OPN mRNA expression exhibited a dose-dependent increase. Low dose induced a 2-fold increase while the high dose induced an almost 100 -fold increase. At 4 wk, the mid-dose and high-dose elevated OPN mRNA levels. At 13 wk, the high dose elevated OPN mRNA levels. No significant elevation with mid dose level was observed. At 26 wk, the mid and high dose induced elevated OPN mRNA levels. At 52 wk, rats in the low, mid and high dose groups all indicated elevated levels of OPN mRNA. Specifically, the low, mid and high doses induced a 3-fold increase, 7-fold increase and 400-fold increase, respectively. **OPN Protein in BALF:** Data was not reported at 0 and 4 wk. At 13 wk, protein increased 9-fold (~800 pg/mL OPN) at mid dose and 100 -fold (~8000 pg/mL OPn) at high dose. At 26 wk, the mid and high dose groups remained elevated. At 52 wk, protein increased by 2.5 fold in low dose, 7-fold in mid dose and 166-fold in high dose group. **Histopathology:** At 52 wk, slight OPN immunoreactivity was observed in control and low dose group (immunostaining mostly limited to intraalveolar MACS).Trichrome-stained lung sections from control and low dose groups showed no increase in collagen. Rats exposed to mid or high dose groups showed areas of lesions.
Reference: Martin et al. (2007, 096366) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 1-2 mo	UAP-BA: Urban Air particles (Buenos Airs, Argentina) **Particle Size:** <2.5 µm	**Route:** Intranasal Installation **Dose/Concentration:** 0.17 mg/kg **Time to Analysis:** 3×day, 3 days/wk, 2 days apart (1, 4, 7 day). Parameters measured 1 h post-exposure.	**Particle Characteristics:** 3 types, ultrafines <0.2 um (inorganics ND), bunched agglomerates of ultrafines and <40 um with aluminum silicates, ions and trace metals. **BALF Cells:** Increased amount of phagocytes in alveolar area, reducing airspace percentage (control 52.9% ± 1.39, UAP-BA 24.7% ± 2.87). Increased number of PAS positive cells. **Morphometry:** Induced focal inflammatory lesions. Accumulation of refractile material in upper and lower respiratory tract. PM in phagocytes of bronchiolar lumen and alveolar space. No evidence of fibrosis and/or collagen changes.

Pre-exposure: Vagotomy (sectioning of vagus nerve) or atropine, 1 mg/kg i.p. administered 30 min prior, 2 and 4 h post.	**BALF Cells:** A 9-fold increase in neutrophils with high individual variability in response was observed. Bilateral vagotomy prior to DEP reduced neutrophil increase to 3 fold. Vagotomy with saline instillation had no effect. Atropine reduced neutrophils to levels similar to saline response. No differences were observed between DEP response in anesthetized when compared to conscious animals. Macrophages, eosinophils and lymphocytes remain unchanged. **Respiratory Response:** RMV increased post DEP. Vagatomy reduced response by one-third. Atropine pre-treatment did not have effect.
Reference: Medeiros et al. (2004, 096012) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 60 days **Weight:** 20-30 g	CP: Carbon particles PSA: ROFA (solid waste incinerator hospital Sao Paulo, Brazil) PSB: electric precipitator, steel plant, Brazil) PSA/PSB Characteristics: Generally, PSB had greater component concentrations than PSA: Br (100+x), Cr (3x), Fe (10+x), Mn (2x), Rb (60+x), Se (7x), Zn (4x). PMA>PMB: Ce (3x), Co (10+x), La (100x), Sb (15x), V (50x). **Particle Size:** CP: 1.7 ± 2.5 µm (78%<2.5 µm); PMA: 1.2 ± 2.2 µm(98 %<2.5 µm); PMB: 1.2 ± 2.2 µm (98%<2.5 µm)	**Reference:** Intranasal Instillation **Dose/Concentration:** CP: 10 µg/mouse; 0.5 mg/kg PSA: 0.1, 1 or 10 µg/mouse; 0.005, 0.05, 0.5 mg/kg PSB: 0.1, 1 or 10 µg/mouse; 0.005, 0.05, 0.5 mg/kg **Time to Analysis:** Single, 24 h	**BALF Cells:** No change in BAL cell count was seen. Quantitative cellular counts increased for perivascular area for both groups at all dose levels. Inflammatory cells in alveolar septum area only increased for PSA.
Reference: Mutlu et al. (2006, 155994) **Species:** Mouse **Strain:** C57BL/6 **Age:** 6-8 wk **Weight:** 20-25 g	PM_{10} Collected by baghouse from Dusseldorf, Germany **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 100 ng/mouse; 1 µg/mouse; 10 µg/mouse; 100 µg/mouse **Time to Analysis:** 1-7 days	**Alveolar Fluid Clearance:** At 100 µg/mouse, decreased clearance peaked at 24 h and recovered at 7 days. **Histology:** Evidence of mild lung injury at doses of 100 µg/mouse or more was seen. **BALF Cells:** Significant increase in total cell number was observed. Neutrophils increased but this was not statistically significant. **Wet/Dry Ratio:** Exposure did not induce any effects. **Na, K-ATPase:** At 100 µg/mouse, decreased activity of Na, K-ATPase in basolateral membranes was observed.
Reference: Nadziejko, et al. (2002, 087460) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 16 wk	CAPs: produced at Tuxedo, NY laboratory using centrifugal aerosol concentrator FA: Fine Particle Sulfuric Acid Aerosol UFA: Ultra-Fine Particle Sulfuric Acid Aerosol **Particle Size:** CAPs: $PM_{2.5}$; FA: 160 nm; UFA: 50-75 nm	**Route:** Nose-only Inhalation **Dose/Concentration:** CAPS 80, 66 µg/m^3; avg 73 µg/m^3 FA: 299, 280, 119, 203 µg/m^3; avg 225 µg/m^3 UFA: 140, 565, 416, 750 µg/m^3; avg 468 µg/m^3 **Time to Analysis:** 10 exposures of 4 h each, each exposure at least 1 wk apart. (2 exposures to CAPs, 4 to FA and 4 to UFA)	**Respiratory Rate:** CAPs decreased the respiratory rate as did FA at all dose levels. However, the FA-induced respiratory rate was not statistically significant unless the data was combined. UFA increased this rate significantly.
Reference: Nemmar et al. (2007, 156800) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 16 wk **Weight:** 424 ± 8g	DEP: SRM 2975 **Particle Size:** <1 µm	**Route:** Intravenous Injection **Dose/Concentration:** 0.02, 0.1 or 0.5 mg/kg **Time to Analysis:** single, 24 h	**BALF Cells:** Marked cellular influx at all dose levels Was observed. Macrophages increased at the high dose, but this was not statistically significant. PMN increased significantly at all dose levels. **Wet/Dry Ratio:** All dose levels induced increases.

Reference: Nemmar et al. (2003, 087931) **Species:** Hamster **Gender:** Male and Female **Weight:** 100-110 g	PS: Polystyrene particles PSC: Polystyrene particles, Carboxylate modified PSA: Polystyrene particles, Amine modified **Particle Size:** PS, PSC, PSA-60: 60 nm; PSA-400: 400 nm	**Route:** IT Instillation **Dose/Concentration:** 5, 50 or 500 µg/animal; 0.05, 0.5, 5 mg/kg **Time to Analysis:** Single, 10 min post-exposure Rose Bengal administered to induce thrombosis, immediate study thereafter	**BALF Cells:** Both PSA-60 and PSA-400 (PSA-60>PSA-400) induced a massive influx of PMNs. PSA-60 effect may exhibit some dose-dependency. **BALF Inflammatory/Injury Markers:** Small increases in total protein were seen at 500 µg level for both PSA-60 and PSA-400. LDH was increased at all PSA-60 levels but not for 500 ug PSA-400. Histamine increased for all PSA-60 levels and PSA-400 but due to high variability only the effect at 500 µg PSA-60 was statistically significant.
Reference: Nemmar et al. (2003, 097487) **Species:** Hamster **Gender:** NR **Weight:** 100-110 g	DEP: SRM 1650 **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 50 µg/animal **Time to Analysis:** Single exposure, parameters measured 1, 3, 6 or 24 h post- exposure.	**BALF Cells:** DEP led to a significant PMN flux at 1 h (13% of total cell number), 6 h (22%) and 24 h (37%). **Histamine:** Concentrations in BALF were consistently elevated starting at 1 h. Plasma histamine did not increase until 6 h. **Pretreatment with Histamine Receptor Antagonist:** A major decrease in DEP induced PMN infiltration was seen. No effect on histamine in BALF or plasma was observed.
Reference: Pereira et al. (2007, 156019) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 3 m	Ambient Particles (Porto Allegre, Brazil) **Particle Size:** <10µm	**Route:** Whole-body Inhalation **Dose/Concentration:** P-6: 34, 22 or 225 µg/m^3 P-20: 139 or 112 µg/m^3 P-I: 99 µg/m^3 **Time to Analysis:** P-6: single/continuous for 6 h P-20: single/continuous for 20h P-I: intermittent (5 h) periods per day for 4 days consecutively Parameters measured 0 or 24 h post-exposure	**BAL Inflammatory/Injury Markers:** An increase in lipid peroxidation was statistically significant only for the 20 h continuously exposed group. Leukocytes also increased at P-20. No change at P-6. Total protein remained unaffected at all dose levels. **Wet to Dry Ratio (0h):** No effect was observed.
Reference: Pinkerton et al. (2004, 087465) **Species:** Rat **Gender:** Female (pregnant), Offspring- NR **Strain:** SD **Age:** 10 days (pups), Pregnant females- 10-14 days of gestation **Weight:** NR	PM (Fe and soot from combustion of acetylene and ethylene in a laminar diffusion flame system) **Particle Size:** Median diameter: 72-74 nm; size range: 10-50 nm	**Route:** Inhalation **Dose/Concentration:** Mean mass concentration: 243 ± 34 µg/m^3; Average Fe concentration: 96 µg/m^3 **Time to Analysis:** Exposed 10 days postnatal age, 6 h/day, 3 days (consecutive).	A significant reduction of cell proliferation occurred only within the proximal alveolar region of exposed animals compared to controls. There were no significant differences between the groups for alveolar formation and separation within the proximal alveolar region.
Reference: Pinkerton et al. (2002, 087645) **Species:** Rat **Gender:** Male, Female **Strain:** SD **Age:** 11-13 wk (adult male), 10-12 days (neonatal) **Weight:** NR	PM (Fe, Soot) (ethylene, iron pentacarbonyl, acetylene combined; Fe_2O_3; soot: 60% EC, 40% OC) (CO, NO_X) **Particle Size:** Fe (diameter) 40 nm; Soot (primary particles, diameter) 20-40 nm	**Route:** Whole-body Inhalation **Dose/Concentration:** Adult males: Fe- 57, 90 µg/m^3, Soot- 250 µg/m^3, Fe+Soot- Fe: 45 µg/m^3, Total PM: 250 µg/m^3; Neonates: Fe+Soot- Low: Fe- 30 µg/m^3, Total PM: 250 µg/m^3, High: Fe- 100 µg/m^3, Total PM: 250 µg/m^3 **Time to Analysis:** Adult males exposed to Fe, soot, Fe+Soot, or filtered air. Exposed 6 h/d, 3 days (consecutive). BAL, 2 h postexposure, lung tissue, 24 h postexposure. Neonatal rats exposed to Fe+Soot 10-12 day-old and 23-25 day-old.	**Fe:** Only the high dose had significant effects. This dose increased total protein in the lavage fluid, decreased total antioxidant power, induced GST activity, and induced a non-significant, increasing trend of GSH and GSSG. IL-1β, intracellular ferritin, and NF-κB increased. **Fe+Soot, Soot:** Fe+Soot significantly reduced the total antioxidant power in BALF and supernatant from lung tissue homogenate. Fe+Soot significantly increased GSSG, IL-1β, NF-κB, CYP1A1, and CYP2E1. CYP2B1 increased but was not significant. Soot alone was not significant for anything. **Neonates:** The high-dose significantly decreased cell viability, increased LDH activity, and increased IL-1β and ferritin. Both doses significantly increased GSSG, GRR, and GST, and decreased total antioxidant power.

Reference: Pires-Neto et al. (2006, 096734) **Species:** Mouse **Gender:** Male **Strain:** Swiss **Age:** 6 days	Ambient Air: $PM_{2.5}$, NO_2 and CB (Sao Paulo, Brazil) **Particle Size:** $PM_{2.5}$	**Route:** Whole-body Inhalation **Dose/Concentration:** $PM_{2.5}$: 46.49 µg/m^3 Control: 18.62 µg/m^3 NO_2: 59.52 µg/m^3 Control: 37.08 µg/m^3 CB: 12.52 µg/m^3 Control: 0 µg/m^3 **Time to Analysis:** 24 h/day, 7 days/wk for 5 mo (weaned at 21 days into exposure, mothers removed)	**Nasal Cavity:** Increased total mucus and acidic mucus at proximal and medial areas of cavity. Nonsecretory epithelium declined. No significant changes in amount of neutral mucus, volume proportion of neutral mucus, volume proportion of total mucus, thickness of epithelium, volume proportion of nonsecretory epithelium or ratio between neutral and acidic mucus were observed. **Types of Acidic Mucus Cells:** Proximal and medium cells increased. Effects on distal cells were equivocal.
Reference: Pourazar et al. (2005, 088305) **Species:** Human **Gender:** Male and Female (nonatopic & nonsmokers) **Age:** 21-28 yr	DEP: generated from idling Volvo diesel engine DEP 300 µg/m^3 comprised of: NO_2 1.6 ppm NO 4.5 ppm CO 7.5 ppm Hydrocarbons 4.3 ppm Formaldehyde 0.26 mg/m^3 Suspended particulates 4.3×10^6/cm^3 **Particle Size:** <10 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** DEP 300 µg/m^3 **Time to Analysis:** Single exposure for 1 h. Parameters measured 6 h post exposure.	**Transcription Factors:** Exposure induced increased cytoplasmic and nuclear immunoreactivity of phosphorylated p38 MAPK in bronchial epithelium. Increased nuclear translocation of phosphorylated p38 and JNK, MAPK as well as increased nuclear phosphorylated tyrosine immunoreactivity were observed. No change in total or nuclear c-fos immunoreactivity was seen. Exposure induced increased nuclear translocation of phosphorylated JNK significantly associated with phosphorylation of nuclear c-jun and also resulted in an increase in nuclear p65. **Cytokines:** Expression of IL-8 was positively associated with nuclear phosphorylated p38 post-exposure.
Reference: Pradhan et al. (2005, 096128) **Species:** Rat **Gender:** Female **Strain:** Wistar Albino **Weight:** 120-180 g	RSPM: Respirable Suspended PM (Lucknow, India) Quartz dust (positive control) **Particle Size:** < 5 µm	**Route:** IT Instillation **Dose/Concentration:** 2.5, 5.0, or 10.0 mg/ 0.05 ml; 20, 42, 83 mg/kg **Time to Analysis:** 15 days.	**Relative Lung Weight:** A dose-dependent increase in total lung weight of RSPM-instilled animals was observed. **BALF Cells:** Exposure induced a dose-dependent increase in total cells dose-dependent with the low and mid dose levels. PMNs increased massively at all dose levels with RSPM inducing less of an increase than Quartz. Exposure at low dose levels resulted in an influx of inflammatory cells (predominantly macrophages into lumen of alveolar ducts and alveoli). Reaction at the high dose was more intense than that seen in mid dose-exposed lungs. **BAL Inflammatory/Injury Markers:** A significant dose-dependent increase in LDH and NO was observed, but the Quartz-induced increase was greater than the RSPM-induced increase. An increase in protein was significant at the mid dose level for RSPM and significant at the high dose level for both RSPM and Quartz. **Lung Biochemistry:** An increase in lipid peroxidation was dose-dependent. Superoxide dismutase (SOD) enzyme levels showed a dose-dependent decrease.

Reference: Rao et al. (2005, 095756) **Species:** Rat **Strain:** SD **Weight:** 175 g	DEP: SRM 2975 **Particle Size:** 0.5 µm	**Route:** IT Instillation **Dose/Concentration:** 5, 35, 50 mg/kg bw **Time to Analysis:** Sacrificed 1, 7, 30 days post single exposure. Cytokines measured after 24 h incubation (in vitro).	**BALF Cells:** Macrophages unaffected. Increased PMNs at 1 day for all dose levels, sustained elevation at 7days for mid and high dose and at 30 days for all dose levels. **BAL Inflammatory/Injury Markers:** Increased albumin at 1 and 30 days at all dose levels. Increased LDH except at low dose at 7 days. **Cytokines:** The high dose induced a significant increase of mRNA expression for IL-1β, iNOS, MCP-1, and MIP-2 in BAL cells. MCP-1 mRNA sustained high levels at 7 days for mid and high dose and at 30 days for all dose levels. mRNA expression of IL-6, IL-10, TGF-β1, TNF-α were unaffected. However, IL-6 and MCP-1 proteins increased significantly in BALF at 1 day for mid and high dose, returning to basal levels at 7 days. MIP-2 increased for all dose levels at all time points. NO level unaffected.

Reference: Rhoden et al. (2004, 087969) **Species:** Rat **Gender:** Male **Strain:** SD **Weight:** 250-300 g	CAPs (Boston, MA) **Particle Size:** CAPS: 0.1-2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 1060 ± 300 µg/m^3 **Time to Analysis:** Single exposure for 5 h. Analyzed 24 h post-exposure. (CAPS-NAC = CAPS with 50 mg/kg bw NAS (N-acetylcysteine) pretreatment)	**Particle Characteristics:** Major components did not appear to show any correlation to total particle mass. Included Na, Mg, Al, Si, S, Cl, K, Ca, Ti, V, Cr, Mn, Fe, Ni, Cu, Zn, Br, Ba, Pb. Metals Al, Si and Fe (somewhat less for Pb, Cu, K) correlated with TBARS. **BALF Cells:** CAPS increased PMN 4 fold. NAS treatment reduced this increase to control levels. **BAL Inflammatory/Injury Markers:** LDH and total protein not affected. Histology confirms slight inflammation with CAPS and no inflammation with CAPs-NAC. **Oxidative Stress:** CAPS increased TBARS and oxidized protein by 2+ fold. NAS fully prevented the increase in TBARS and partially prevented an increase in protein carbonyl. **Tissue Damage:** Wet/dry ratio increased with CAPS but significantly decreased with NAC.
Reference: Rhoden et al. (2008, 190475) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** NR **Weight:** 300 g	Urban Air Particles (UAP) (SRM 1649) **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 1mg in 100 µL saline **Time to Analysis:** Instilled with UAP. CL analysis:15 min post-exposure. BAL measurements: 4 h post-exposure. Some rats pre-treated with MnTBAP 2 h prior to UAP exposure.	UAP significantly increased the total cell number, PMN, MPO activity, and protein levels. MnTBAP prevented UAP-induced lung inflammation. UAP increased oxidants in lung CL, which was prevented by MnTBAP.

NF-κB activity increased at 6 h but was not statistically significant.
Reference: Saber et al. (2005, 097865) **Species:** Mouse **Gender:** Female **Strain:** TNF(-/-) (B6, 129S-Tnftm1Gk1), C57/BL **Age:** 9-10 wk	DEP: SRM 2975 CB: Printex 90 (Degussa) **Particle Size:** DEP: 215 nm; CB: 90 nm	**Route:** Nose-only Inhalation **Dose/Concentration:** DEP: 20 mg/m^3; CB: 20 mg/m^3 **Time to Analysis:** 90 min/day for 4 days consecutively, 1 h	**BALF Cells:** Neutrophils increased significantly to 15% when compared to control (4%) with DEP exposure. No response difference was observed between TNF (+/+) and TNF(-/-). CB did not induce any changes in neutrophil numbers. **Cytokines:** IL-6 increased 2-3 fold in DEP and CB exposure in both normal and knockout mice. IL-1β was unaffected. **mRNA:** In TNF (+/+) mice, DEP and CB increased expression of TNF mRNA 2- fold. IL-6 mRNA expression was high in DEP-exposed knockout mice when compared to normal mice. **DNA:** DNA strand breaks increased in both strains. Knockout mice showed a higher response to CB and DEP exposure. For normal mice, only CB induced a statistically significant effect.

Reference: Schins et al. (2004, 054173) **Species:** Rat **Gender:** Female **Strain:** Wistar Kyoto **Weight:** 350-550 g	Soluble fractions PMC: $PM_{10-2.5}$ PMF: $PM_{2.5}$ -B: Borken, Germany (rural) -D: Duisburg, Germany (industrialized) **Particle Size:** $PM_{10-2.5}$, $PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** 0.32 ± 0.01 mg/rat; 0.91± 0.58 mg/kg **Time to Analysis:** Single, 18 h	**BALF cells:** Both PMC showed a massive increase in neutrophils. PMC-B induced the greatest increase followed by PMC-D. Both PMF did not induce a significant increase. **BAL Inflammatory/Injury Markers:** PMC from both sites induced markedly higher endotoxin concentration vs PMF as follows in decreasing order: PMC-B, PMC-D, PMF-B, PMF-D, control. Glutathione decreased only for PMC-B. LDH and total protein were unaffected. **Cytokines:** TNF-α and IL-8 increased with PMC from both sites. PMF induced a slight increase in IL-8 but did not induce an increase in TNF-α. **Radical Formation:** Formation of hydroxyl radicals increased with exposure. Relative intensity was: PMC-D, PMF-D, PMC-B, PMF-B, and control.
Reference: Seagrave et al. (2005, 088000) **Species:** Rat **Gender:** Male **Strain:** F344/DCrl BR **Age:** 11 ± 1 wk	PM from 3 sources: NT: New Technology bus, Detroit Diesel 50G, exhaust oxidation catalyst, 216 miles, 2002 model - in use NE: Normal emitter bus, Detroit Diesel 50G, no catalyst, 134259 miles, 1997 model - in use HE: High Emitter bus, Cummins L10G, no catalyst, >250, 000 miles, 1992, retired Fuel composition very similar for 3 vehicles: methane (96-96.8%), ethane (1.6-1.9%), carbon dioxide (0.9-1.1%), nitrogen (0.6-0.8%), traces of other gases **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 0.25-2.2 mg/rat in 0.5mL saline **Time to Analysis:** Single, 24 h	**Engine Specific Emission data:** HE had significantly higher PM and SVOC recovered emission rates than NE and NT. **Organic mass in PM:** The following PM sources are listed in decreasing order of percent of total mass: HE, NE, NT. **Total PAH:** The following PM sources are listed in decreasing order of total mass: HE, NT, Control, NE. **Nitro PAH:** The following PM sources are also listed in decreasing order of total mass: NE, HE, Control, NT. Authors note confounding technical issues (mostly technique related) with mostly mild effects. **BAL Inflammatory/Injury Markers:** LDH showed dose-dependent increases with HE inducing higher increases than NT and NE. Total protein exhibited dose-dependent increases with HE, NT and the positive control SRM2975 inducing higher levels than NE. **Potency Factors Cytotoxicity and Inflammation:** HE was significantly more potent than NT and NE, with NT also showing significant potency. **Lung Toxicity:** The results were highly variable but the general toxicity levels in increasing order is the following: NE, NT, HE, Normal gasoline, diesels, and high gasolines, though individual factors may differ greatly.
Reference: Seagrave et al. (2006, 091291) **Species:** Rat **Gender:** Male **Strain:** F344/Crl BR, **Age:** 11 ± 1 wk	$PM_{2.5}$ sources: BHM: Birmingham, Alabama; urban JST: Jefferson Street, Atlanta, Georgia; urban PNS: Pensacola, Florida; urban/residential CTR: Centreville, Alabama; rural "smoke" = downwind of forest fires/burns (NR) **Particle Size:** $PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** 0.75, 1.5, 3 mg/rat **Time to Analysis:** Single, 24 h	**BALF PMN:** In general, the winter samples induced greater increases in potency than the summer samples except for PNS. For the winter samples, the samples that induced the greatest increases, in descending order, are: JST, BHM, CTR, PNS and Smoke. For the summer, the samples that induced increases, in descending order, are: BHM, JST, PNS, and CTR. **BALF Macrophages:** For the winter, the BHM and JST samples significantly increased potency whereas the PNS sample induced significantly negative potency. For the summer, only the BHM sample significantly induced potency. **BALF Lymphocytes:** Only the JST-W and BHM-W significantly increased potency. The BHM-S, CTR-S and PNS-S also significantly increased potency. **Histopathology:** All the winter and summer samples, excepting PNS, significantly induced inflammation. **Lung weight/body Weight Ratio:** In general, for all end points, JST-S was significantly less potent than JST-W. The summer samples of BHM and CTR were also generally more potent than their winter counterparts.

MIP-2 decreased for both genders at 1000 HWS. TNF-α decreased in females with DE exposure. No TNF-α effects for HWS were observed. **BAL Inflammatory/Injury Markers:** LDH was unaffected by DE. Exposure to HWS induced an increase for males only at 100 and 300 but not at 1000 µg/m^3. Protein was unaffected by DE. HWS exposure showed male-only effects at 100 and 300 µg/m^3 but not at 1000. AP was unaffected by DE or HWS except for slight decline induced by HWS at 1000 µg/m^3 for both genders. **Other:** β-glucose was unaffected by DE. HWS-exposed females showed decreased β-glucose at 100 and 300 but not at 1000 µg/m^3. **BALF GSH to (GSH+GSSG):** No effects for DE were observed. HWS significantly decreased the ratio in both males and females at 1000 µg/m^3. The effect for females was greater than the male effect.
Reference: Seagrave et al. (2008, 191990) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 10-12 wk **Weight:** 250-300 g	GEE (2 1996 General Motors 4.3-L V6 gasoline engines; conventional Chevron Phillips gasoline, U.S. average composition) (CO, NO, NO_2, SO_2, THC) ($PM_{2.5}$ composition-EC, OC, SO4, NH4, NO_3) Simulated downwind coal emission atmospheres (SDCAs) (fly ash, gas-phase pollutants, sulfate aerosols, NO, NO_2, SO_2) Paved Road Dust (RD) (Los Angeles, CA; New York City, NY; Atlanta, GA) **Particle Size:** GEE: MMAD- 150 nm, RD: 2.6 ± 1.7 µm, SDCA: 0.1-1.0 µm	**Route:** Nose-only Inhalation **Dose/Concentration:** GEE: 60 µg/m^3, SDCAs: 317-1072 µg/m^3, RD: 306-954 µg/m^3; GEE: CO-104 ppm, NO- 16.7 ppm, NO_2- 1.1 ppm, SO_2-1.0ppm, THC- 12 ppm; SDCAs: CO- <1 ppm, NO-0.19-0.62 ppm, NO_2- 0.10-0.37 ppm, SO_2- 0.07-0.24 ppm, THC- <1 ppm **Time to Analysis:** 6 h exposure, immediately post-exposure	GEE produced CL in the lungs, heart, and liver. RD produced a significant effect in the heart at the low dose. SDCAs had no effect on CL. GEE did not affect the amount of macrophages or PMN. SDCAs increased macrophages. The RD low dose increased macrophages and PMN. SDCAs increased Penh values and tidal volumes.
Reference: Singh et al. (2004, 087472) **Species:** Mouse **Gender:** Female **Strain:** CD-1 **Age:** 6-8 wk	A-DEP (4cyl light duty 2.7l Isuzu diesel at 6 kg/m) DEP: SRM 2975 **Particle Size:** A-DEP >50 µm	**Route:** Oropharyngeal Aspiration **Dose/Concentration:** 25 or 100 µg/mouse **Time to Analysis:** single, 4 h (18 h post-exposure measurements taken but NR due to similar results)	**Particle Characteristics:** DEP had 60% EC vs 9% in A-DEP. A-DEP had 50% OC vs 5% in DEP. Phenanthrene and Fluoranthene fractions were much more prevalent in PAH from DEP than A-DEP. **BALF Cells:** PMNs significantly increased dose-dependently with DEP and remained elevated at 18h. Endotoxin induced the greatest increases of PMNs. Macrophages increased with A-DEP and were unaffected by DEP. **Cytokines:** Endotoxin induced massive responses for IL-6, MIP-2 and TNF-α but no response from IL-5. A-DEP increased all 4 cytokines but only at the 100 µg dose level. Similarly, DEP only increased IL-6 at the 100 µg dose level. **BAL Inflammatory/Injury Markers:** Microalbumin increased for both pollutants except DEP induced increases only at 100 µg. Endotoxin increased microal-bumin. NAG increased with 100 µg A-DEP.

Reference	Pollutant	Exposure	Effects
Reference: Smith et al. (2003, 042107) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 11-12 wk	CAPs (Fresno, CA) **Particle Size:** <2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 6 exp in 2 sets of 3: Fall1 = 847 µg/m^3 Fall2 = 260 µg/m^3 Fall3 = 369 µg/m^3 Winter1 = 815 µg/m^3 Winter2 = 190 µg/m^3 Winter3 = 371 µg/m^3 **Time to Analysis:** 4 h/days for 3 consecutive days. Parameters measured immediately following last exposure.	**Particle Characteristics:** Nitrate showed the highest variability near 10 fold, followed by Si, S and EC. OC concentration was relatively consistent. Metals otherwise appeared proportionate to the concentrations. **BALF Cells:** Total cells increased at wk1. Percent of macrophages reduced in wk2 with CAPs. Number of neutrophils increased with CAPs, but only achieved statistical significance during wk1 of the fall and winter. Lymphocytes increased but were not statistically significant. **BAL cell permeability**: Upon CAPs exposure, the proportion of nonviable cells were increased up to 242% when compared to controls. The fall of wk2 induced the highest significant increases followed by fall wk1, fall wk3, and winter wk3.
Reference: Smith et al. (2006, 110864) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 8 wk **Weight:** 260-270 g	CFA: Coal Fly Ash (400 MW, Wasatch Plateau, Utah) (aerodynamic separation) **Particle Size:** 0.4-2.5 µm	**Route:** Nose-only Inhalation **Dose/Concentration:** 1400 µg/m^3 $PM_{2.5}$ including 600 µg/m^3 PM_1 **Time to Analysis:** 4 h/days for 3 consecutive days. Parameters measured 18 or 36 h post-exposure.	**BALF Cells:** Percent and total number of neutrophils in BALF and blood increased significantly at both 18 and 36 h. Percent of macrophages decreased slightly while number of macrophages increased in bronchiole-alveolar duct regions at both time periods. **Cytokines:** MIP-2 and transferrin increased at 18 h. IL-1β increased at 36 h. **Other:** Gamma glutamyl transferase decreased at 36 h. Lung antioxidant increased at 18 h.
Reference: Song et al. (2008, 156093) **Species:** Mouse, **Gender:** Female **Strain:** BALB/c **Age:** 5-6 wk	DEP collected from a 4JB1-type, light-duty (2740 cc), four-cylinder diesel engine operated using standard diesel fuel at speeds of 1500 rpm under a load of 10 torque. **Particle Size:** 0.4 µm (mean diameter)	**Route:** Intranasal Instillation (days 1-5), Whole-body Inhalation (days 6-8) **Dose/Concentration:** 0.6 mg/mL in 50 µL of saline (days 1-5), 6mg/m^3 for 1 h/day for 3 days (days 6-8). **Time to Analysis:** Enhanced Pause (Penh), measured on day 9. BAL and lung tissues collected on day 10.	**Airway Hyperresponsiveness:** Intranasal exposure plus aerosolized DEP caused a significant increase in methacholine-induced Penh over the control. **BAL Analysis:** There was no significant increase in IFN-γ in the BAL fluid following DEP treatment but there was a significant increase in IL-4 levels compared to the control. (IL-4 increase could indicate that DEP modulates Th-2 cytokines in the mouse model). DEP also induced an increase in total neutrophils and lymphocytes in the BAL when compared to the control. The nitrite concentration in BAL (indicating NO generation) was significantly greater in the DEP exposed group than the control. **Histology:** Peribronchial and perivascular infiltrates were more common in the group exposed to DEP than the control. **Ym1 and Ym2 Expression:** (see explanation in comments section) Ym1 and Ym2 transcripts were upregulated in response to DEP exposure in mice.
Reference: Steerenberg et al. (2006, 088249) **Species:** Rat **Strain:** Crl/WKY **Age:** 6-8 wk	Ambient air samples PMC, PMF: -I: Rome, Italy -N: Oslo, Norway -PL: Lodz, Poland -NL: Amsterdam, Netherlands Measured Components: Li, Be, B, Na, Mg, Al, K, Ca, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, As, Se, Sr, Mo, Cd, Sn, Sb, Ba, Ce, Nd, Sm, Au, Hg, Tl, Pb, Bi, U, Si, Endotoxins, Cl, NO-, SO4 **Particle Size:** PMC: 2.35-8.5 µm; PMF: 0.12-2.35 µm	**Route:** IT Instillation **Dose/Concentration:** 1 and 2.5 mg/animal **Time to Analysis:** Single, 24 h	**Particle Characteristics:** Concentrations of metals were highest in Rome. Amsterdam was noted for high Mg and V. Lodz was noted for high Pb, Zn, PAH. More of PMC was composed of Fe, Mn, Al, Cr, Cu. More of PMF, on the other hand, was composed of Zn, Pb, Ni, V. **BALF Cells:** PMNs increased. **Cytokines:** MIP-2 increased dose-dependently. TNF-α also increased. **BAL Inflammatory/Injury Markers:** CC16 decreased substantially. Crustal material (endotoxin, Na, Cl and metals but not Ti, As, Cd, Zn, V, Ni, Se) was positively associated with short term CC16. Albumin increased.

Reference	Pollutant	Exposure	Effects
Reference: Stinn et al. (2005, 088307) **Species:** Rat **Gender:** Male and Female **Strain:** Crl: (WIU BR **Age:** 40 days	DE (generated from 1.6 L VW diesel under USFTP 72) CO: 10, 37 ppm CO_2: 2170, 6540 ppm NO: 7.0, 22.8 ppm NO_X: 8.6, 28.3 ppm SO_2: 0.83, 3.09 ppm NH_4: ND Measured Major Components: NO, SO_2, 1-nitropyrene, Zi. 50% by DE weight is EC. **Particle Size:** 0.19-0.21 µm (MMAD)	**Route:** Nose-only Inhalation **Dose/Concentration:** 3 and 10 mg/m^3 **Time to Analysis:** 6 h/day, 7 days/wk for 24 mo; 6 mo. post-exposure	**Body Weight:** Mean weight increased substantially during the first few weeks in all groups. Food consumption decreased in 1-24 mo but was recovered in 24-30 mo. Body weight decreased at 23 mo in all categories, but recovered except in high dose males at 30 mo. **Organ Weight:** Absolute weight of lungs, larynx and trachea increased from 0 to 12 to 24 mo and stayed elevated at 30 mo: Low<Hi, male ~ female. **Pulmonary Parameters:** Respiratory frequency, tidal volume, and minute volume were unaffected in any group measured between 3 and 24 mo. EC increased dose-dependently in exposure groups. No male/female difference was observed, but increases were greater at 24 mo than at 18 mo. **BALF Cells:** PMNs and lymphocytes showed dose and time-dependent effects at 18 and 24 mo (no data at 30 mo). Lymphocytes increased 50 fold in high dose males at 24 mo. Peripheral monocytes and neutrophils increased 3 fold in DE groups at the end of the study. Particle-filled macrophages in alveolar lumen and interstitium increased at 12, 24, 30 mo in both genders at all dose levels. **BAL Inflammatory/Injury Markers:** LDH increased in dose and time-dependent manner. **Nasal Cavity Histopathology:** All effects were resolved at 30 mo. Nasal cavity hyperplasia increased at the high dose at 12 and 24 mo in both genders. Squamous metaplasia of respiratory epithelium increased in high dose females (12, 24 mo). **Larynx Histopathology:** No effects were observed. **Lung Histopathology:** Alveolar region hyperplasia of alveolar epithelium increased at 12, 24, 30 mo in both genders at all dose levels except for 12 mo low dose males and females. Above lung histopathology was not time-dependent, though perhaps some small dose-dependence was observed. The following histopathology findings showed strong dose- and time-dependent increases that occurred in both genders (24-30 mo): goblet cell hyperplasia of bronchial epithelia, cuboidal/columnar hyperplasia of alveolar epithelium, chronic active inflammation and septal fibrosis. **Tumorigenicity:** Lung tumors were more prevalent in females than males and appeared to be dose-dependent. The major 3 types of tumors are the following:: bronchio-alveolar adenoma, bronchiolo-alveolar adenoma and benign keratinizing cystic cell tumors. Enhanced effects in females versus males may be the result of enhanced metabolism (body volume versus body weight) and increased respiratory volume/bw for females.

Total cell count, macrophages and eosinophils were unaffected. Leukocytes and lymphocytes increased, though not significantly. **Cytokines:** GE caused time-dependent increases in TNF-α and IL-6. IL-10 and IL-1β were unaffected. **BAL Inflammatory/Injury Markers:** γ-GGT, ALP and LDH increased after 2 wk of GE exposure and stayed stable at 21 days. Total protein slightly increased on 14 and 21 days, though these increases were not statistically significant. **Histopathology:** Minor changes at 7 days, mild edema in alveolar region at 14 days and sloughing of epithelial cells in bronchiolar region and focal accumulation of inflammatory cells in alveolar region at 21 days were observed in a time-dependent manner.
Reference: Tesfaigzi et al. (2002, 025575) **Species:** Rat **Gender:** NR **Strain:** Brown-Norway **Age:** 7-8 wk **Weight:** 310-330 g	WS (wood stove- Vogelzang Boxwood Stove, Model BX-42E, wood- Pinus edulis) (CO, NO, NO_X, total hydrocarbon) **Particle Size:** Smaller size fraction: 0.405-0.496 µm, larger size fraction: 6.7-11.7 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** Target concentration (low, high exposure): 1, 10 mg/m^3; CO- 15-106.4 ppm, NO- 2.2-18.9 ppm, NO_X- 2.4-19.7 ppm, total hydrocarbon- 3.5-13.8 ppm **Time to Analysis:** 3 h/day, 5 days/wk, 4 or 12 wk.	**Respiratory Function:** Total pulmonary resistance increased for exposure groups and was significant for the low-exposure group. In exposed groups, forced expiratory flows and quasistatic compliance were lower and dynamic lung compliance higher, the latter being significant for the high-exposure group. For the high-exposure group, vital capacity slightly decreased, residual volume slightly increased, and CO-diffusing capacity had a slight, significant decrease. **BALF Cells:** Macrophages decreased significantly in the high-exposure group. Particle-laden macrophages increased with concentration. Lymphocytes and neutrophils slightly increased in the high-exposure group. **Cytokines:** LDH increased slightly and protein levels decreased slightly in the high-exposure group. Cytokines were below detectable levels. **Histopathology:** WS caused minimal to mild chronic inflammation in the epiglottis of the larynx. PAS-positive cells increased in the 30 day high-exposure group. AMs increased with time and concentration. Particle-laden macrophages were seen after 90 days. AB- and PAS-positive epithelial cells increased for the 90 day low exposure group.
Reference: Tin-Tin-Win-Shwe et al. (2006, 088415) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 7wk	CB14: Printex 90 (Degussa) CB90: Flammruss 101 (Degussa) **Particle Size:** CB14: 14 nm CB95: 95 nm	**Route:** IT Instillation **Dose/Concentration:** 25, 125, 625 µg/mouse; approx. 1, 5, 25 mg/kg **Time to Analysis:** 1/wk for 4wk. 4 h post-exposure	**Body Weight, Thymus, Spleen, Splenic Cell Count:** No effects were observed. **BALF Cells:** Increased total cell numbers were observed for 125, 625 µg CB14 (dose-dependent) and 625 µg CB95. Total cell count was twice as high for CB14 at 125 and 625 µg compared to CB95. AM numbers exhibited a dose-dependent response for both CB14 and CB95 for all doses except 125 µg. Lymphocyte numbers increased at 125 and 625 µg for CB14 and 625 µg for CB95. PMN numbers increased at 125 and 625 µg for CB14 and CB95, but the response was greater with CB14. PMN numbers were proportional to dose surface area for both PM sizes. **BAL Cytokines:** CB14 and CB95 induced dose-dependent increases in IL-1β. TNF-α increased at 125 and 625 µg dose in CB14 with the 125 dose inducing a slightly greater increase. CB14 and CB95 induced CCL-3 increases 125 and 625 µg. **Chemokine mRNA in lung and lymph nodes:** CCL-3 mRNA increased for CB14 but not CB95 4 h following the last exposure. CCL-2 was unchanged. **Mediastinal lymph nodes:** The number of CB-laden phagocytes increased in a dose-dependent manner for CB14 and CB95. CB14 had higher numbers at all doses compared to CB95.

Reference	Pollutant	Exposure	Effects
Reference: Tong et al. (2006, 097699) **Species:** Mouse **Gender:** Male **Strain:** KP600 CD-1 **Weight:** 22-26 g	$PM_{2.5}$ (collected from stacked filter air sampler in Shanghai, China) Fe: $FeSO_4$ Zn: $ZnSO_4$ PMF: $PM_{2.5}$ + $FeSO_4$ PMFZ: $PM_{2.5}$ + $FeSO_4$ + $ZnSO_4$ Major Measured Components: Fe 26 ppm, Zn 9 ppm, S 61 ppm **Particle Size:** $PM_{2.5}$	**Route:** IT Instillation **Dose/Concentration:** PM: 25 mg/mL, 1mg/mouse Fe: 15mg/mL, 0.6 mg/mouse Zn: 15mg/mL, 0.6 mg/mouse PMF: PM 25 mg/mL + Fe 15 mg/mL, 1.6 mg/mouse PMFZ: PM 25 mg/mL + Fe 15 mg/mL, 1.6 mg/mouse **Time to Analysis:** Instilled twice at 0 and 24 h. Parameters measured 24 h following last exposure (at 48 h).	**Synchrotron X-ray imaging:** PMFZ showed the greatest increase in alveolar changes. Fe induced more hemorrhagic changes, whereas Zn induced more nonuniformity of lung texture. This suggests that Zn induces PBMC in a dose-dependent manner which releases IL-1, IL-6, TNF-α, and IFN-γ. **Histopathology:** PMFZ induced the most severe changes including serious inflammation/pus in bronchia and bronchial epidermal cell hyperplasia. For Fe or PMF hemorrhagic changes predominated but were less severe than PMFZ.
Reference: Upadhyay et al. (2008, 159345) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 6 mo. **Weight:** NR	Ultrafine Carbon Particles (UFCP) **Particle Size:** Size- 31 ± 0.3 nm, MMAD- 46 nm, Surface area concentration- 0.139 m^2 particles/m^3, Mass specific surface area- 807 m^2/g	**Route:** Whole-body Inhalation **Dose/Concentration:** 172 µg/m^3 **Time to Analysis:** 24 h exposure. 4 days recovery. Sacrificed 1st or 3rd day of recovery.	**Pulmonary Inflammation:** UFCP did not cause pulmonary inflammation. **Pulmonary and Cardiac Tissue:** HO-1, ET-1, ETA, ETB, TF, PAI-1 significantly increased in the lung on the 3rd recovery day. HO-1 was repressed in the heart, but the other markers had slight, nonsignificant increases.
Reference: Wallenborn et al. (2007, 156144) **Species:** Rat **Gender:** Male **Strain:** WKY, SH,, and stroke-prone SH (SHRSP) **Age:** 12-15 wk	PM: precipitator unit power plant residual oil combustion **Particle Size:** PM: 3.76 µm (bulk) ± 2.15	**Route:** IT Instillation **Dose/Concentration:** WKY vs SHRSP: 1.11, 3.33, 8.33 mg/kg SH vs SHRSP: 3.33, 8.33 mg/kg **Time to Analysis:** Single, 24 h Note: 4 h post-exposure study done on WKY vs SHRSP but not published.	**BALF Cells:** A dose-dependent increase in total cells and neutrophils was observed. Equal response for all 3 strains except for SH, for both concentrations was observed. **BAL inflammation/Injury Markers:** LDH exhibited a dose-dependent increase in equal response for all 3 strains. WKY had higher baseline levels of NAG activity but, upon PM exposure, SHRSP induced higher increases than WKY. GGT exhibited a dose-dependent response for all 3 strains. SHRSP showed the highest increase followed by WKY and SH. Protein levels increased at the high dose level with SHRSP exhibiting the highest increases followed by SH and WKY. Albumin levels were inconsistent between experiments. **Oxidative Stress - Lung:** (WKY vs SHRSP only): SOD decreased following increased exposure levels with SHRSP levels generally higher than WKY. Ferritin levels declined only in SHRSP. **GPx:** No action but SHRSP levels were similar to SHR and, in the WKY vs SHRSP experiment, SHRSP exhibited higher activity level than WKY. **Ferritin:** Equivocal results were observed. Levels decreased at the high dose for WKY and SHRSP but increased at medium doses for SH and SHRSP. **ICDH:** Levels increased for WKY and decreased for SHRSP.
Reference: Wallenborn et al. (2008, 191171) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 13 wk **Weight:** NR	Zinc Sulfate ($ZnSO_4$, aerosolized) **Particle Size:** NR	**Route:** Nose-only Inhalation **Dose/Concentration:** 9.0 ± 2.1 µg/m^3, 35 ± 8.1 µg/m^3, 123.2 ± 29.6 µg/m^3 **Time to Analysis:** Exposed 5 h/days, 3 days/wk, 16 wk. Half of the rats used for plasma/serum analysis, other half for isolation of cardiac mitochondria.	A trend toward increased BALF protein was seen. No pulmonary-related effects were seen.

Reference	Pollutant	Exposure	Effects
Reference: Wegesser and Last (2008, 190506) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 8-10 wk	Ambient $PM_{2.5-10}$ Collected from San Joaquin Valley, CA **Particle Size:** $PM_{10-2.5}$	**Route:** IT Instillation **Dose/Concentration:** 25-50 µg/mouse **Time to Analysis:** 3, 6, 18, 24, 48, 72 h post IT instillation.	**BALF Cells:** Increased amount of viable cells found in PM-exposed mice with dose-response relationship between dose of PM and number of total cells recovered in BALF. At 6 h, increased numbers of macrophages at both 25 and 50 µg/mouse. Increased percentage of neutrophils observed with 50 µg/mouse PM only. Furthermore, both macrophages and neutrophils increased with longer time period from instillation, peaking at 24 h. At 50 µg/mouse, MIP-2 concentrations increased, peaking at 3 h, though not statistically significant and returned to basal levels by 6 h. Positive correlation observed between MIP-2 concentration and increased neutrophil counts. No correlation found between MIP-2 and macrophages.
Reference: Whitekus et al. (2002, 157142) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 6-8 wk **Weight:** NR	DEP (light-duty, four-cylinder engine- 4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) **Particle Size:** 0.5-4 µm	**Route:** Inhalation **Dose/Concentration:** 200, 600, 2000 µg/m^3 **Time to Analysis:** Exposed 1 h/day,10 days. Animals receiving OVA had 20 min OVA exposure after DEP exposure.	DEP+OVA dose-dependently increased IgE and IgG1, being more effective than the OVA-alone treatment. This effect was significantly suppressed by thiol antioxidants NAC or BUC. DEP+OVA increased carbonyl protein and lipid peroxide over OVA. NAC or BUC suppressed lipid peroxide and protein oxidation. No general markers for inflammation were observed.
Reference: Wichers et al. (2004, 055636) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 75 days	PM (HP-12): inside wall of stack of Boston, MA power plant burning # 6 oil. **Particle Size:** PM: 3.76 µm ± 2.15	**Route:** IT Instillation **Dose/Concentration:** 0.83, 3.33 or 8.33 mg/kg **Time to Analysis:** single, 6 h for Whole-body plethysmographs (WBP) and repeated daily for 4-7 days, 96 or 192 h post-exposure non-WBP animals: single, 24, 96, 192 h post-exposure	**Tidal Volume:** A dose-dependent decrease in tidal volume (45 % at high dose) was sustained for 1 day with very slow recovery over 7 days. **Breathing Frequency:** Dose-dependent increase (100 % at high dose) with recovery at 7 days was observed. **Minute Ventilation:** Small dose-dependent increases were observed with a return to normal ventilation in 2 days. **Penh (enhanced pause):** Equivocal results in all groups were observed (due to major control variation). **BALF Cells:** Dose-dependent increases in total cells at 24 h, with declined, but still elevated, levels at 192 h. Neutrophils increased significantly (10 fold) at 24 h in the mid and high dose groups and showed declined, but still elevated, levels at 192 h. Macrophages slowly increased in a dose-dependent manner at 192 h. **BAL Inflammatory/Injury Markers:** Protein and albumin increased at 24 h, returned to relative basal level at 192 h at the mid and high dose levels. NAG exhibited dose-dependent increases at 24 h and sustained these levels through 192 h.
Reference: Wichers et al. (2006, 103806) **Species:** Rat **Gender:** Male **Strain:** SH **Age:** 71-73 days **Weight:** 255-278 g	PM (HP-12): inside wall of stack of Boston, MA power plant burning # 6 oil. **Particle Size:** 1.95 µm ± 3.49	**Route:** Whole-body Inhalation **Dose/Concentration:** 13 mg/m^3 **Time to Analysis:** Phase I: 1st day, filtered air, 2nd day, 6 h of PM Phase II: 1st day filtered air, 4 days of 6 h PM each Immediate post-exposure	**Body/ Lung Weight:** No effects on Phase I rats were observed. HP-12 exposure increased body weight, left lung, right intercostal, and right diaphragmatic lobes in Phase II rats. However, results appeared due to normal growth in juvenile rats over 4 days. **Lung lobe to Body Weight Ratio:** No effects at 1 or 4 days were observed. **Deposition calculations:** V and Co were used to estimate deposition rates (good correlation between two metals at R_2 = 0.94). Total HP-12 deposition using Co was 26 and 99 µg (for 1 day and 4 day experiments) and using V was 31 and 116 µg. Modeling information estimated HP-12 deposition at 43% in conducting airways and 57% in alveolar region. **Breathing parameters:** No changes were observed for 1 or 4 days studies except for a possible decrease in frequency for the 1 day study.

Reference: Witten et al. (2005, 087485) **Species:** Rat **Gender:** Female **Strain:** F344 **Age:** 8 wk **Weight:** ~175 g	DEP (heavy-duty Cummins N14 research engine operated at 75% throttle) **Particle Size:** 7.234-294.27 nm	**Route:** Nose-only Inhalation **Dose/Concentration:** Low- 35.3 ± 4.9 µg/m^3, High- 632.9 ± 47.61 µg/m^3 **Time to Analysis:** Exposed 4 h/day, 5 days/wk, 3 wk. Pretreated with saline or capsaicin.	There were no differences for substance P. The low-exposure group had significantly less NK1. DEP reduced NEP activity. Plasma extraversion dose-dependently increased and was greatest in capsaicin animals. Respiratory permeability dose-dependently increased. IL-1β was significantly higher for the low-exposure group. IL-12 was significantly lower in the capsaicin high-exposure group. TNF-α increased in the high-exposure group and capsaicin low-exposure group. High exposure induced particle-laden AMs in the lungs, perivascular cuffing consisting of mononuclear cells, alveolar edema and increased mast cell number. Neutrophil and eosinophil influx was not seen.
Reference: Wong et al. (2003, 097707) **Species:** Rat **Gender:** Female **Strain:** F344/NH **Age:** ~4 wk **Weight:** ~175 g	DEP (Cummins N14 research engine at 75% throttle) (EC-34.93-601.67 µg/m^3, OC- 1.90-11.25 µg/m^3, Sulfates 0.94-17.96 µg/m^3, Na- 4.07-4.78 ng/m^3, Mg-0.60-0.86 ng/m^3, Ca- 5.05-10.66 ng/m^3, Fe- 3.17-6.44, Cr- 0.68-1.31 ng/m^3, Mn- 0.11-0.22 ng/m^3, Pb- 0.97-1.24 ng/m^3) **Particle Size:** 7.5-294.3 nm	**Route:** Nose-only Inhalation **Dose/Concentration:** Low- 35.3 ± 4.9 µg/m^3, High- 669.3 ± 47.6 µg/m^3 **Time to Analysis:** Exposed 4 h/day, 5 days/wk, 3 wk. Pretreated with saline or capsaicin.	DEP dose-dependently increased plasma extraversion, which was further increased by capsaicin. In the high-exposure group, particle-laden AMs (which were reduced by capsaicin), inflammatory cell margination, perivascular cuffing with subsequent mononuclear cell migration and dispersal, increased mast cells, and decreased substance P were all seen. NK-1R was downregulated in the low-exposure group and upregulated in the capsaicin-pretreated high-exposure group. NEP decreased significantly for both groups.
Reference: Wu et al. (2003, 199749) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 60 days	Zn^{2+} **Particle Size:** NA	**Route:** IT Instillation **Dose/Concentration:** 50 µm/rat **Time to Analysis:** Single, 24 h	**Cells:** Decreased number of airway epithelial cells shown with PTEN protein immunostaining. Macrophages were unaffected.
Reference: Yamamoto et al. (2006, 096671) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 7 wk **Weight:** 23 g	CB14: Printex 90 (Degussa) CB95: Flammruss 101 (Degussa) LTA: Lipoteichoic acid 14CL: CB14 + LTA 95CL: CB95 + LTA CB14 measured Components: C 96.79%, HR 0.19%, N0.13%, S 0.11%, Ash 0.05%, O 2.74% CB95 measured Components: C 97.98%, HR 0.15%, N 0.28%, S 0.46%, Ash 0%, O 1.14% **Particle Size:** CB14: 14 nm; CB95: 90 nm	**Route:** IT Instillation **Dose/Concentration:** CB14: 0, 25, 125, 625 µg/mouse CB95: 0, 25, 125, 625 µg/mouse LTA: 10 or 50 µg/mouse 14CL: 125 µg CB14 + 10 or 50 µg LTA 95CL: 125 µg CB95 + 10 or 50 µg LTA **Time to Analysis:** Single, 4 and 24 h	**BALF Cells:** CB95 induced dose-dependent increases of PMN. CB14 induced an increase in PMNs but the increases were not dose-dependent. LTA massively increased PMN. LTA induced dose-dependent increases in total cells, especially at high dose at 24 h. LTA had massive synergistic effect with CB14 and CB95 for total cells and PMNs. Total cell count and PMN levels were highest in 14CL with levels at 24 h higher than at 4 h. Macrophage data were inconsistent. **Cytokines:** CB95 induced dose-dependent increases in IL-6, TNF-α, CCL2 and CCL3. CB14 induced dose-dependent increase in CCL2 and CCL3. Exposure induced increases of IL-6 at the high dose only. Slight effect on TNF-α was observed. LTA induced dose-dependent increases of IL-6, TNF-α and CCL3. 14CL massively induced IL-6 and CCL2. No combination of CB and LTA affected TNF-α or CCL3. **mRNA Expression:** LTA, 14CL and 95CL increased TLR_2 mRNA expression with 95CL and 14CL inducing higher increases than LTA. No effect on TLR4 mRNA expression was observed.

Reference: Yanagisawa et al. (2003, 087487) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6 wk **Weight:** 29-33 g	DEP: (4JB1 light duty 4cyc 2, 74 liter Isuzu engine) LPS DEP-OC: organic compounds DL: DEP + LPS DOL: DEP-OC + LPS **Particle Size:** 0.4 µm	**Route:** IT Instillation **Dose/Concentration:** DEP/DEP-OC: 125 µg/mouse LPS: 75 µg/mouse **Time to Analysis:** Single, 24 h	**BALF Cells:** DEP and DEP-OC increased neutrophils but the increases were not statistically significant. LPS increased neutrophils significantly. DL and DOL massively increased neutrophils at greater levels than LPS alone. Macrophages were unaffected. **Cytokines:** LPS increased IL-1β, MIP-1α, MCP-1 and KC. DEP and DEP-OC had no effect. DL induced further increases. DOL decreased cytokines compared to LPS alone. DEP-OC increased IL-1β and MIP-1α mRNA expression slightly. DEP had no effect. LPS significantly increased IL-1β and MIP-1α mRNA expression. DL increased expressions while DOL did not. **Pulmonary Edema:** LPS, DEP and DEP-OC increased edema. DL further increased this effect. DOL had no effect compared to LPS alone. **Histology:** DL elevated neutrophil inflammation interstitial edema and alveolar hemorrhages. DOL induced neutrophilic inflammation without the alveolar hemorrhages. **mRNA Expression of TLRs:** DEP-OC, DL, DOL and LPS increased TLR_2. DEP had no effect. All particles increased TLR4 mRNA expression.
Reference: Yokohira et al. (2007, 097976) **Species:** Rat **Gender:** Male **Strain:** F344/DuCrj **Age:** 10 wk	DQ-12: Quartz dust (Douche Montan) HT: Hydrotalcite (Kyoward 500, PL-1686, KYOWA) POF: Potassium Octatitanate fiber (TISMO, Otsuka) PdO: Palladium Oxide CB: Carbon Black (Mitsubishi Kasei) **Particle Size:** DQ12 <7 µm HT: 7.8 ± 1.5 µm POF: <50 um length; <2 µm width PdO: 0.54 ± 1.11 µm CB: 28 nm	**Route:** IT Instillation **Dose/Concentration:** 4 mg/rat in 0.2 ml saline **Time to Analysis:** Single, 1 and 28 days	**Lung Weight/Body Weight Ratio:** DQ-12, HT and POF induced increases after 1 day. After 28 days, all samples induced increases in lung weight. **BALF Cells:** Neutrophils increased significantly in walls and alveolar spaces in all groups on 1 day except at HT. At 28 days, this increase was maintained only in walls with severe and moderate elevations, except for DQ-12. **Histopathology:** DQ-12 caused pulmonary edema both at 1 and 28 days. PdO and CB induced edema at 28 days. Fibrosis was observed after 28 days with the most significant increase, in decreasing order, induced by DQ-12,PdO, POF, HT, CB, and the control. Histiocyte infiltration was observed after 1 day for DQ-12, POF and PdO. At 28 days, infiltration was observed for DQ-12, HT, POF and PdO. Restructuring of alveolar walls and microgranulation was observed for all 5 particles but only at 28 days with DQ 12, PdO, HT, POF, CB and control. **Immunohistochemistry:** BrdU: At 1 day all 5 particles elevated in both area and number. Activity declined after 28 days but was still higher than the control. **iNOS:** At 1day DQ-12, POF and PdO induced increases. At 28 days, DQ-12 and HT induced increases. **MMP-3:** DQ-12 induced increases at both 1 and 28 days and PdO at 28 days. **Toxicity scoring:** The levels of toxicity are, in decreasing order, as follows: DQ-12, HT/PdO/POF, and CB.

Reference: Zhao et al. (2006, 100996) **Species:** Rat **Strain:** SD **Age:** NR **Weight:** 200 g	DEP: SRM 2975 DEPE: SRM 1975 **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 35 mg/kg **Time to Analysis:** Single, 1 day AG group coexposed 30 pre and 3, 6, 9 h post DEP/DEPE	**iNOS Expression in AMs:** Both DEP and DEPE increased 12 and 6 fold respectively. NO and peroxynitrite levels increased accordingly. AG had no effect on iNOS expression but AG attenuated NO for both DEP and DEPE but peroxynitrite only for DEPE. DEP induced much higher levels of oxidants than DEPE. Unlike DEPE, DEP was unaffected by AG. **Role of iNOS in Lung Injury:** DEP and DEPE induced inflammation (PMN), cellular toxicity (LDH) and lung injury (protein). AG significantly attenuated the DEPE response but no effect was observed on the DEP responses. **Cytokines:** IL-12 levels were induced by both DEPE and DEP, with DEPE inducing higher increases than DEP, and both were significantly attenuated by AG. DEP and DEPE induced similar increases in IL-10 levels. AG increased DEP effect 3 fold and attenuated DEPE to control. **CYP Enzymes:** DEP and DEPE induced increases in CYP1A1 level and activity. AG attenuated CYP1A1 activity for both DEP and DEPE. CYP2B1 level and activity were slightly decreased by DEP and DEPE. AG had no effect. **Cytosol Phase II Enzymes:** DEPE had no effect; AG treatment increased catalase activity. DEP reduced catalase and GST activities. AG had no effect. Neither DEP, DEPE nor AG affected QR quinone reductase.
Reference: Zhou et al. (2003, 087940) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 10-12 wk	UFe: Ultrafine Fe particles **Particle Size:** 72 nm	**Route:** Whole-body Inhalation **Dose/Concentration:** 57 or 90 μg/m^3 **Time to Analysis:** 6 h/days for 3 days, parameters measured within 2 h post-exposure.	**BALF Cells:** No significant changes observed in total cell number, cell viability or cell differentials. **Cytokines:** Only at the high dose was an increase in IL-1β observed. No effect on TNF-α or NF-κB-DNA binding activity was observed. **BAL Inflammatory/Injury Markers:** At the high dose, total protein increased. No significant changes were observed in LDH. **Intracellular Ferritin:** The high dose induced increases. No significant differences were observed between the low dose and control. **Oxidative stress:** Antioxidant level by FRAP value decreased at the high dose. GST (glutathione-S-tranferase) activity increased at the high dose. No effect on intracellular GSH and GSSG (glutathione disulfide) was observed.

Table D-4. Effects related to immunity and allergy.

Reference: Apicella et al. (2006, 096586) **Species:** Mouse **Strain:** BALB/c **Cell Line:** 112D5 hybridoma Primary Macrophages: Peritoneal	Poly OVA (Ovalbumin on polystyrene beads) Soluble OVA **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** PolyOVA and Soluble OVA: 0.2,1.0 or 5.0 µg/mL **Time to Analysis:** 48 h	**IL-6:** Stimulation with PolyOVA higher than stimulation with soluble OVA **TNF-α:** Stimulation with PolyOVA higher than stimulation with soluble OVA. **IL-10:** No modifications in levels after PolyOVA or soluble OVA stimulation. **Viability of Peritoneal Macrophages:** Stimulation with PolyOVA led to 33% decrease in viability. Stimulation with soluble OVA led to 24% in viability. **Effects of PolyOVA Stimulated Macrophages:** Culture supernatants from PolyOVA stimulated macrophages had a percentage increase of asymmetric IgG; however, the addition of rmIL-6 at identical concentrations did not induce a significant increase. It also decreased the proliferation of 112D5 hybridoma.
Reference: Arantes-Costa et al. (2008, 187137) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 6 wk **Weight:** NR	ROFA (solid waste incinerator powered by combustible oil; São Paulo, Brazil) **Particle Size:** NR	**Route:** Intranasal Instillation **Dose/Concentration:** 60 µg ROFA in 50 µL saline **Time to Analysis:** OVA sensitized days 1 and 14. OVA-challenged days 22, 24, 26, and 28. ROFA exposed 1-3 h after OVA challenge or saline. Pulmonary responsiveness measured day 30 then sacrificed. Lungs removed, fixed for 48 h.	ROFA increased pulmonary responsiveness and decreased ciliated cells in nonsensitized mice, which were both further amplified in the presence of OVA. ROFA did not affect eosinophils, macrophages, chronic inflammation, or neutral or acidic mucus.
Reference: Archer et al. (2004, 088097) **Species:** Mouse **Strain:** BALB/c DO11.10+/+ transgenic - ova specific receptor for OVA peptide 323-339 **Age:** 4 wk	PM = SRM 1648 (NIST) TiO_2 **Particle Size:** SRM1648: avg 1.4 µm TiO_2: avg 0.3 µg (sic)	**Route:** Intranasal instillation **Dose/Concentration:** 500 µg/30 µl sterile saline, initial 0-750 µg range finding **Time to Analysis:** Ova challenge at 68 h, Methacholine aerosolization/AR at 72 h	**Airway responsiveness (WBP):** AR induced by Ova/Mch challenge was significantly and dose-dependently increased at doses of SRM1648 ≥500 µg . TiO_2/Ova exposure was not significantly different from saline. PM associated endotoxin did not contribute to enhanced AR. **Lung inflammation/pathology:** No increases in BAL macrophages or eosinophils and no histological alterations after PM exposure. Both TiO_2 and PM increased pulmonary neutrophils, indicating particles alone were responsible for this increase and that the inflammatory response could occur independently of AR.
Reference: Barrett et al. (2006, 155677) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 8-10 wk	HWS (black/white oak) CO Total Vapor Hydrocarbon (TVH) **Particle Size:** 0.25 ± 3.3, 0.35 ± 2.5, 0.35 ± 2.0, 0.36 ± 2.1 µm (MMAD±GSD)	**Route:** Whole-body Inhalation **Dose/Concentration:** HWS: 30, 100 300, 1000 µg/m^3 CO: 0.7, 1.6, 4.0, 13 ppm TVH: 0.3, 0.6, 1.3, 3.1 ppm **Time to Analysis:** Pretreatment: ip 10 µg OVA and 2 mg aluminum hydroxide post-OVA. OVA aerosol challenge on day 14, followed by 3 days of HWS. Pre-OVA received aerosol OVA challenge on day 14, then 3 days of HWS on days 26-28 and an immediate (second) OVA challenge HWS 6 h/day for 3 days. Sacrificed 18 h post-exposure.	**Allergic Inflammation:** A statistically significant increase in eosinophils was observed at 300 µg/m^3 HWS following OVA challenge as compared to OVA alone. No changes in macrophages, neurophils and lymphocytes were observed. Post-OVA HWS did not significantly alter BAL cytokine or serum antibody levels, but linear trend analyses indicated decreases in IL-2, IL-4, and IFN-γ in the absence of OVA, as well as a statistically significant upward trend in OVA-specific IgE when HWS exposure followed OVA challenge. HWS exposure pre-OVA (prior to second OVA challenge) resulted in a decrease in IL-13 (statistically significant at the high dose but no evidence of an exposure-dependent response), an increase in OVA IgG1 (trend significant) and no change in IL-2, IL-4, IL-5, IFN-γ, OVA IgE, total IgE or OVA IgG2a.

Reference: Burchiel et al. (2004, 055557) **Species:** Mouse **Strain:** AJ **Age:** 10-12 wk	DE generated alternatively from two 2000 Cummins ISB Turbo Diesel 5.9 L engines using no 2 (chevron) oil and 15w/40 oil (Rotella T, Shell) run according to USEPA Dynamometer Schedule for Heavy-Duty Diesel Engines 18 PAHs quantified at exposure levels (text mentions 65) **Particle Size:** NR	**Route:** Inhalation **Dose/Concentration:** 30, 100, 300, 1000 mg/m^3 diesel PM **Time to Analysis:** 6 h/day, 7 days/wk for 6 mo.	**Proliferative Responses:** DE depressed splenic T cell proliferation at all exposure levels but was not dose-dependent and most pronounced at the 30 µg/m^3 level. ($p<0.05$ at all levels) Splenic B cell proliferation was increased at the 30 µg/m^3 level, but not at the other exposure levels. Little, if any, PAH was found in DE, and the majority of PAH tested in vitro enhanced T cell proliferation (below), so PAH is likely not responsible for the immunosuppressive effect of DE on murine spleen cell responses.
Reference: Chan et al. (2006, 097468) **Species:** Mouse **Strain:** DO11.10, BALB/c, Nrf 2$^{-/-}$ **Cell Types:** Primary bone marrow dendritic cells and dendritic cell line (BC1), T cells (BMDC)	DEP: DE particles DEP methanol extract: **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** DEP: 10 µg/mL LPS: 5 ng/mL **Time to Analysis:** 24 h	**Dendritic Cell Maturation:** Organic DEP chemicals interfered in the expression of several DC maturation markers. Both DEP and DEP extracts were found to inhibit CD86 expression and IL-12 production in LPS-exposed DCs, and intact particles were not as effective as DEP extract. DEP extract treatment of BC1 cells reduced their ability to stimulate co-cultured antigen-specific T cells, leading to decreased IFN- y and increased IL-10 without affecting IL-4 or IL-13. DEP extract also induced oxidative stress and interfered with DC activation by several other Toll-like receptor agonists as well as the NF-kB cascade. Inhibition of IL-12 production by DEP extract was shown to be mediated by pro-oxidative chemicals that engage the Nrf2 pathway. Taken together the inhibition of both IL-12 and IFN- y indicates a suppression of the Th1 pathway and provides a novel explanation for the adjuvant effect of DEPs on allergic inflammation.

Study	Pollutant	Exposure	Effects
Reference: Ciencewicki et al. (2007, 096557) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 10-12 wk **Weight:** 17-20 g	DE: generated from a 30-kW (40 hp), 4-cylinder Deutz BF4M1008 diesel engine Influenza A/Bangkok/1/79 (H3N2 serotype) from Dr. Melinda Beck of the University of North Carolina, Chapel Hill O_2, CO, NO_2, NO, SO_2 O_2: 20.9- 20.5% (Lo, Hi) CO: 0.9-5.4 ppm NO_2: 0.25-1.13 ppm NO: 2.5-10.8 ppm SO_2: 0.06-0.32 ppm H_3N_2: NR **Particle Size:** NR	**Route:** Inhalation; Oropharyngeal aspiration (virus) **Dose/Concentration:** DE: 529 or 2070 µg/m^3 **Time to Analysis:** 4 h/day for 5 days. Virus exposure immediately after last DE exposure. Analyzed 18 h post infection.	**DE exposure on susceptibility to Influenza Infection:** Mice exposed to 0.5 mg/m^3 had significantly greater levels of HA mRNA compared to air-exposed mice. HA levels not significantly altered in mice exposed to 2.0 mg/m^3. **DE Exposure on the Influenza-induced Inflammatory Response:** f IL-6 mRNA levels were significantly greater when exposed to 0.5 mg/m^3 of DE prior to infection compared to air exposure. Significantly increased amount of IL-6 protein observed in exposed mice. Exposure to DE in absence of influenza infection had no significant effect on IL-6 mRNA or protein levels. **DE Exposure on Pulmonary Injury:** Infection with the influenza virus increases levels of PMN in BAL fluid. Exposure to either dose of DE prior to infection showed no significant effect on PMN levels Exposure to DE alone had no effect on PMNs in BAL fluid. Neither exposure to DE nor infection with influenza significantly increased BAL fluid protein levels when compared to non-infected, air-exposed. **Other Markers of Injury,** NAG and MIA were not statistically affected by DE or influenza exposure. **DE Exposure on the Influenza Induced Interferon Response:** No significant change in TFN-α mRNA levels at either dose of DE, although mice exposed to 0.5 mg/m^3 of DE prior to infection had significantly greater levels of IFN-B MRNA compared to air controls. No effect on any of the IFNs observed in uninfected mice exposed to DE. **DE Exposure on Surfactant Protein Expression:** Influenza virus infection alone significantly increased expression of SP-A in air-exposed. Exposure to 0.5 mg/m^3 of DE prior to infection had significant decreases in levels of SP-A mRNA in the lungs, this effect was not observed in 2.0 mg/m^3 DE exposed. Decrease seen in expression of SP-A protein in lungs of mice exposed to 0.5 mg/m^3 DE prior to infection. Levels of SP-D mRNA and protein were significantly decreased in lungs of mice exposed to 0.5 mg/m^3 of DE prior to infection compared with mice exposed to air or 2.0 mg/m^3 DE prior to infection. Exposure to 0.5 mg/m^3 of DE prior to infection with influenza decreased levels of SP-D, especially in airways. Mice exposed to 2.0 mg/m^3 DE prior to infection showed no significant difference.
Reference: Day et al. (2008, 190204) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 8-10 wk **Weight:** NR	GEE (General Motors 1996 model 4.3-L V6 engine; regular unleaded fuel) (CO, NO, NO_2, SO_2, NH_3) **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** Low(L)- 6.6 ± 3.7 PM/m^3, Medium(M)- 30.3 ± 11.8 PM/m^3, High(H)- 59.1 ± 28.3 PM/m^3, High-Filtered(HF) **Time to Analysis:** Pre-OVA protocol: OVA or saline sensitized 7 days. OVA challenge day 14. GEE or air exposed 6 h/day on days 26-28. Immediately after exposure on day 28 challenged with OVA. Tested for MCh-induced changes 24 h post-exposure then sacrificed. Post-OVA protocol: OVA or saline sensitized 7 days. OVA challenge day 14. GEE or air exposed days 15-17. Tested for MCh-induced changes 24 h post-exposure then sacrificed.	**Pre-OVA:** In nonsensitized mice, neutrophils and IgE decreased in the H group. IL-2 increased in the HF group and was dose-dependent. Eosinophils dose-dependently decreased. OVA-specific IgE increased in the H group, and OVA-specific IgG2a dose-dependently increased. In OVA-sensitized mice, OVA-specific IgG1 increased in the M group. Airway hyperresponsiveness was lower in the M and HF groups. **Post-OVA:** In nonsensitized mice, neutrophils dose-dependently decreased, IL-4 decreased in the M group, IL-5 decreased in the HF group, and IFN-γ decreased at all exposures. In OVA-sensitized mice, IL-13 dose-dependently decreased.

Study	Pollutant	Exposure	Effects
Reference: de Haar et al. (2005, 097872) **Species:** Mouse **Gender:** Female **Strain:** BALB/cANNCrl **Age:** 6-8 wk **Weight:** NR	CBP: Carbon black particles in phosphate buffered saline, 1: 10 & 1: 100 dilutions (Brunschwich Chemicals, Amsterdam, The Netherlands) OVA: Ovalbumin **Particle Size:** CBP: 30-50 nm	**Route:** Intranasal Droplet **Dose/Concentration:** CBP± OVA 200, 20, 2 µg (3.3, 0.33, 0.033 mg/ml) OVA only: 20 µg (0.5 mg/ml) **Time to Analysis:** Droplet applied on days 0, 1, 2. Sacrificed on day 4 or challenged with OVA droplet on days 25, 26, & 27. Sacrificed on day 28	**Acute Airway Damage and Inflammation:** Only day 4 had LDH increased in the 200 µg CBP+OVA group. The 200 µg CBP+OVA group induced significantly higher numbers of BAL cells compared to OVA control. Total protein and TNF-a levels were increased only in 200 µg CBP+OVA group. RAS, parameter for phagocytosis, 200 µg and 20 µg CBP+OVA had higher levels than OVA controls. **Adjuvant Activity on PBLN:** Total lymphocytes in PBLN significantly increased 4-5 fold in the 200 µg CBP+OVA exposed. 20 µg and 2 µg exposures did not increase the number of PBLN cells compared to OVA control. All CBP+OVA concentrations induced higher levels of IL-4, IL-5, IL-10, and IL-13, with 200 µg concentration having 10-200 times higher levels. IFN-y cytokine was increased in the 200 µg dose. **IgE Production:** In CBP+OVA, IgE were significantly increased. **PBLN and Lung Lymphocytes after OVA Challenge:** PBLN cell numbers increased in OVA and CBP+OVA sensitized mice. CD4 and CD8 populations increased in both groups. PBLN levels in CBP+OVA and challenged with PBS were higher than mice treated with OVA and challenged with PBS, both groups cytokine production was low, only IL-5 levels were significant in the CBP+OVA/PBS group. Higher lung lymphocyte numbers were caused by higher numbers of CD4 and CD19. Production of IL-5 and IL-10 was four to five times higher than in OVA treated mice. **OVA Challenge Induces Asthma like Airway Inflammation in CBP+OVA Sensitized Mice:** Total number of cells in BAL increased 10 fold in CBP+OVA mice challenged with OVA. Eosinophils exhibited highest increase in CBP+ OVA/OVA group. Perivascular and peribronchial infiltrates and goblet cell hyperplasia in CBP+OVA/OVA was confirmed by histological examination. Antigen specific inflammation induced in CBP+OVA mice.

Study	Pollutant	Exposure	Effects
Reference: de Haar (2006, 144746) **Species:** Mouse **Gender:** Female **Strain:** BALB/cANNCr **Age:** 6-8 wk **Weight:** NR	CBP: fine (F) and ultrafine (UF) carbon black particles (Ken Donaldson Group) TiO_2: fine and ultrafine OVA: Ovalbumin **Particle Size:** F CBP: 260.0 nm UF CBP: 14.0 nm F TiO_2: 250.0 nm UF TiO_2: 29.0 nm	**Route:** Intranasal Droplet **Dose/Concentration:** CBP: 200 µg (3.3 mg/mL) TiO_2: 200 µg (3.3 mg/mL) OVA: 10 µg CBP+OVA: 200 +10 µg **Time to Analysis:** Days 0,1,2: Exposed to OVA or CBP+OVA. Sacrificed on day 8 & analyzed after 2 h, or continued to second group. Second group: days 25, 26, 27 given OVA challenge day 28: sacrificed , analyzed 24 h post sacrifice	**Ultrafine Particles Induce Lung Inflammation:** UF TiO_2 and CBP induced a local inflammatory response in the airways and showed higher levels of LDH and total protein as compared to mice exposed to the F particles. Cytokine levels were much higher in groups exposed to ultrafine particles. Histologic analysis of the airways showed that exposure to ultrafine TiO_2 or CBP leads to peribronchial and perivascular inflammatory infiltrates (mostly neutrophils). Exposure to OVA alone, or combined with fine TiO_2 and fine CBP had no effects on lung histology. **Ultrafine Stimulate Local Immune Responses:** TiO_2 and CBP particles stimulated the local immune response against co administered OVA antigen. Fine TiO_2 particles induced a low but significant increase in PBLN cell number. Both types of ultrafine particles elicited higher levels of Th-2 associated cytokines, with UF CBP stimulating a greater response. IFN-y production was low, but significantly higher than OVA exposures. **Ultrafine TiO_2 Increase OVA-specific IgE and IgG1 Levels:** Levels of OVA specific IgE were significantly increased in animals exposed to the UF TiO_2+ OVA compared to F TiO_2 or OVA-only. Average IgE level in mice exposed to ultrafine CBP+OVA was not a significant increase. OVA-specific IgG2a not detected in any groups. **Ultrafine Particles Stimulate Allergic Airway Sensitization Against OVA:** At day 28, the PBLN cell numbers were significantly higher in both ultrafine and combination with OVA. Production of OVA specific IL-4, IL-5, IL-10 and IL-13 by PBLN cells was significantly increased in both ultrafine TiO_2 and CBP. IFN-y levels were significantly increased in ultrafine CBP+OVA treated animals. F TiO_2 had low, but significant, increases in IL-4 and IFN-y compared to OVA only. Allergic airway inflammation and Influxes of eosinophils, neutrophils and lymphocytes were only found in both groups exposed to ultrafine particles.
Reference: de Haar (2008, 187128) **Species:** Mouse **Gender:** Female **Strain:** BALB/c, CD80/CD86-deficient, DO11.10 **Age:** 6-8 wk **Weight:** NR	Ultrafine Carbon Black (UFCB) (Brunschwich Chemicals; Amsterdam, The Netherlands) **Particle Size:** Diameter: 30-50 nm	**Route:** Intranasal Exposure **Dose/Concentration:** 20 µg/mL **Time to Analysis:** Exposed days 1, 2, 3. OVA challenge days 25, 26, 27. Spleens and lymph nodes from DO11.10 mice pooled and CD4+ T-cells isolated. Solution injected into tail veins of BALB/c mice day 0. CTLA4-Ig ip injected days 0, 2. PBLN cell suspensions plated, restimulated with OVA 4 day.	UFCB+OVA induced proliferation of CD4+ T-cells, increased cytokine production. UFCB+OVA did not induce any effects in CD80/CD86-deficient mice. UFCB-induced airway inflammation is dose-dependent.

Study	Pollutant	Exposure	Effects
Reference: Dong et al. (2005, 088079) **Species:** Rat **Gender:** Male **Strain:** Brown-Norway (BN/CrlBR) **Age:** NR **Weight:** 200-225 g	DEP: SRM 2975 (NIST, Gaithersburg, MD) OVA: Ovalbumin **Particle Size:** 0.5 µm (MMAD)	**Route:** Inhalation **Dose/Concentration:** DEP: 20.6 ± 2.7 mg/m^3 OVA 40.5 ± 6.3 mg/m^3 **Time to Analysis:** 4 h/dayfor 5 days + OVA 30 min/day1 x wk on days 8,15 & 29. Sacrificed on days 9 or 30.	**Lung Inflammation/Injury:** Both the BAL proteins and inflammatory cell counts for DEP exposure alone were not different from those of the air exposed control, suggesting that DEP exposure did not cause lung injury at 9 or 30 days post-exposure. OVA exposure caused significant increases in neutrophils, lymphocytes, eosinophils, albumin and LDH activity in the lung after two exposures. DEP did show a strong effect on OVA-induced inflammatory responses. **Alveolar Macrophage (AM) function:** OVA exposure resulted in an increase in NO levels in the acellular BAL fluid and AM conditioned media. This increase was significantly attenuated in rats exposed to DEP. DEP exposure had no significant effect on the production of IL-10 or IL-12 by AM recovered from rats 9 and 30 days post exposure. In contrast, OVA sensitization elevated both IL-10 and IL-12 secretion by AM at both time points. **Lymphocyte population and cytokine production:** DEP exposure was found to increase the numbers of total lymphocytes, T cells and their CD4+ and CD8+ subsets in LDLN. OVA exposure also significantly increased these cell counts on days 9 and 30. DEP+OVA exposure showed a significant reduction in total lymphocytes, T cells, CD4+ and CD8+ subsets on day 30. Levels of IL-4 and IFN-y in lymphocyte conditioned media were below detection limit of the ELISA kits. **Intracellular GSH levels in AM and Lymphocytes:** DEP exposure alone slightly decrease GSH levels in AM, but markedly reduced GSH concentration in lymphocytes on days 9 and 30. OVA exposure significantly decreased intracellular GSH in both cell types. Combined exposure showed AM and lymphocytes to have depleted intracellular GSH. **OVA specific IgE and IgG levels in serum:** In all samples collected on day 9, both serum IgG and IgE levels were under the detection limits. On day 30, no measureable IgE levels were found. The OVA exposure, however, resulted in elevated IgE levels, and was enhanced in rats preexposed to DEP. IgE and IgG levels for DEP+OVA was tw0 times higher than OVA alone indicating that DEP has an adjuvant effect on the production of IgG and IgE. **Effects of DEP and OVA on Lung iNOS expression**: AM from various exposure groups did not stain for iNOS. 1 rat at day 9 from the combined DEP+OVA group showed a slightly positive iNOS staining. On day 30, 2 of 5 rats from combined exposure group and 1 from the OVA group showed a positive airway staining.

Study	Pollutant	Exposure	Effects
Reference: Dong et al. (2005, 088083) **Species:** Rat **Gender:** Male **Strain:** Brown-Norway (BN/CrlBR) **Age:** NR **Weight:** 200-225 g	DEP: SRM 2975 Diesel Exhaust Particles (NIST) OVA: Ovalbumin **Particle Size:** 0.5 µm (MMAD)	**Route:** Nose-only Inhalation **Dose/Concentration:** DEP 22.7 ± 2.5 mg/m^3 OVA 42.3 ± 5.7 mg/m^3 **Time to Analysis:** Day 1, 8, 15: OVA exposure 30 min/day Days 24-28: DEP exposure 4 h/day Day 29: OVA challenge Day 30: Whole-body plethysmography Day 31: Sacrifice	**Effect of DEP on OVA Induced Allergic Responses:** DEP exposure had a synergistic effect with OVA on inducing airway hyper-responsiveness (AHR) in rats. DEP alone had no effect on IgG production. Levels of OVA-specific IgG and IgE increased in OVA+DEP exposure. This indicates that DEP pre-exposure augments the immune response of rats to OVA in the production of allergen specific IgG and IgE. **Effect of DEP on OVA Induced Cell Differentiation:** Neither DEP, OVA nor the combination induced elevated levels of LDH activity or albumin content, indicating that the exposure protocols did not cause significant lung injury. DEP alone induced moderate but significant increase of neutrophil numbers. OVA exposure induced a greater infiltration of neutrophils than DEP, and infiltration of eosinophils and lymphocytes. OVA-induced eosinophil count markedly increased with DEP exposure. Total lymphocytes, T cells, and their CD4+ and CD8+ subsets in LDLN from rats sensitized and challenged by OVA were significantly higher than those of air-exposed non sensitized rats. DEP+OVA exposure resulted in substantial increase in T cells compared to OVA alone. **Effect of DEP on OVA-induced Oxidant Generation and GSH Depletion:** Exposure to DEP or OVA alone had no effect on ROS production by AM. Substantial elevation seen in ROS for the DEP+OVA exposed group. Both OVA and DEP exposures resulted in an increased presence of NO in the acellular BAL fluid and in AM conditioned media; OVA+DEP exposure further increased these levels. The ATII cells from OVA exposed rats exhibited a higher percentage of cells that produce NO and superoxide than air exposed, non sensitized rats. DEP and OVA exposure resulted in a significant increase in the percentage of cells that produce NO and superoxide over the control. **iNOS Expression:** Immunohistological analysis in lung tissues showed no AM staining in any group. Airway epithelium was found to be positive in all 5 rats from the DEP+OVA group and 3 of 5 rats from single exposure of DEP or OVA and 2 of 5 in air only exposed rats. iNOS expression was significantly higher in ATII cells isolated from rats exposed to combined DEP and OVA . **GSH levels in AM and lymphocytes:** Levels were slightly lowered by DEP or OVA exposure, though not statistically significant. DEP+OVA showed a significant reduction in GSH levels.

Study	Pollutant	Exposure	Effects
Reference: Drela et al. (2006, 096352) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 6 wk **Weight:** NR	ASM: Air suspended PM from Upper Silesia (Poland) 1µg of ASM: Pb (1.136 ng) Cu (0.004 µg) Co (0.072 ng) Mn (0.406 ng) Fe (0.016 µg) Cd (0.154 ng) Cr (0.418 ng) Ni (0.238 ng) **Particle Size:** 0.3-10 µm	**Route:** Intraperitoneal Injection **Dose/Concentration:** 170 mg/kg **Time to Analysis:** Single, 72 h	**CD28 Expression on Thymocytes at Different Stages of Development:** ASM exposure accelerated thymocyte maturation but did not alter the expression of CD28 on peripheral CD4 and CD8 T cells isolated from lymph nodes. A slight but not statistically significant decrease in the expression of CD28 on spleen T cells from ASM animals was observed. **Distribution of CD28(low) and CD28(high):** Acute exposure to ASM resulted in the increase of CD28(low) and decrease of CD28 (high) thymocyte percentages in the total thymocyte population. The percentages of CD28 low and high thymocytes did not differ between intact and PBS controls. Acute ASM exposure resulted in the increase of the percentage of CD28(low) and the decrease of CD28(high) thymocytes in the CD3 low subset. The percentage of CD28 low and high positive thymocytes did not differ in CD3 high thymocyte subset. **Natural Regulatory CD4+ CD25+ T Cells in the Thymus:** The development of thymic natural regulatory cells was unaffected by ASM. **Proliferation of Splenocytes and Lymph Node Lymphocytes:** Decreased proliferative responses were evident in splenocytes from ASM-exposed animals when cells were stimulated with low but not high levels of anti-CD3 mAb. In contrast, lymph node lymphocytes from ASM treated mice had increased proliferative responses independent of anti-CD3 concentration. Both CD4+ and CD8+ T cells from ASM treated mice proliferated more vigorously than from controls. Almost all CD8+ T cells from ASM mice were induced to proliferate.
Reference: Dybing et al. (2004, 097545) **Species:** Mouse **Gender:** NR **Strain:** BALB/cA **Age:** NR **Weight:** NR	UP: Urban ambient particles collected in 5 different sites (Amsterdam, Lodz, Oslo, Rome, Dutch seaside) during four-wk periods in spring, summer, winter seasons from March 2001 to March 2004. DEP as reference std: SRM 1650 (NIST) OVA: Ovalbumin (Sigma Chemical, St. Louis, MO) **Particle Size:** UP: PM_{10} and $PM_{2.5}$	**Route:** Injection in hind foot pad **Dose/Concentration:** UP: 100- 200 µg DEP: 50 µg OVA: 50 µg **Time to Analysis:** Day 0: 1 exposure to OVA alone, OVA w/particles, particles alone. Day 6: Lymph nodes harvested Day 21: 1 OVA w/o particles exposure Day 26: Antibody assay	**Allergy Screening:** All samples were immunostimulatory in the popliteal lymph node assay; activity was weak in the absence of OVA but statistically significant when injected with OVA, indicating an adjuvant effect. Particle adjuvancy was further demonstrated via significant enhancement of OVA-specific antibody responses. All ambient particle fractions from all seasons increased IgG1. Except for a few coarse samples, all fractions significantly increased IgE. All fine fractions and some coarse fractions significantly increased IgG2a, indicating that most particles could exert both Th1 and Th2 adjuvancy. In general, fine particles demonstrated stronger adjuvant activity than coarse in a pair-wise comparison of coarse and fine particles from the same location.
Reference: Dybing, et al. (2004, 097545) **Species** Rat **Cell Lines:** Type 2 cells, AM	UP: Urban ambient particles collected in 5 different sites (Amsterdam, Lodz, Oslo, Rome, Dutch seaside) during four-wk periods in spring, summer, winter seasons from March 2001 to March 2004. DEP: SRM 2975 (NIST) OVA: Ovalbumin (Sigma Chemical, St. Louis, MO) **Particle Size:** PM_{10} and $PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** 0-50 µg/ml **Time to Analysis:** 20 h	**Inflammation:** The coarse fractions were more potent than the fine fractions. Among the samples, the overall effects of the coarse fractions on the cells were dependent on the site of collection. High MIP-2 levels were found using particles from some spring collections. Coarse particles collected in summer demonstrated the highest potency, and samples collected during winter proved to be less potent but seasonal variation was not obvious for all sites. Only minor responses were observed using fine fractions from urban sites.

Reference: Farraj et al. (2006, 141730) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 6 wk **Weight:** NR	DEP: SRM 2975 NIST OVA: Ovalbumin Anti-p75: Rabbit anti-mouse p75 neurotrophin receptor polyclonal antibody (Chemicon, Temecula, CA) Anti-trkA: anti-mouse trkA NGF receptor antibody (Santa Cruz, Santa Cruz, CA) **Particle Size:** DEP: 1.47 µm (MMAD), 2.75 GSD	**Route:** Nose-only Inhalation **Dose/Concentration:** DEP: 1.78 to 2.18 mg/m^3 Anti-p75: 50 µl Anti-trkA: 50 µl OVA injection: 20 µg MCH: 0, 16, 32, 64 mg/ml **Time to Analysis:** On day 0: ip injection of 20 µg OVA Day 14: intranasal instillation of 50 µl anti-p75 or anti-trkA, 1 h after 1st exposure challenged with OVA aerosol for 1 h followed by a h exposure to DEP 24 h after DEP exposure: MCH challenge	**Airways Responsiveness:** No significant differences in avg baseline Penh values of any treatment groups. Vehicle sensitized mice: exposure to DEP, anti-p75 or anti-trkA had no effect on MCH-induced Penh values. OVA-sensitized DEP-exposed: seen increase of Penh values**.** Administration of anti-p75 or anti-trkA to OVA sensitized mice reversed DEP induced Penh increases. **Lung Function in Ventilated Mice:** Compared to vehicle sensitized mice, central airway resistance (Rn) increased 62% in OVA sensitized mice was not a significant increase. OVA-sensitized DEP-exposed mice, anti-p75 decreased central airway resistance (Rn) and anti-trkA did not significantly alter Rn. though Rn response for anti-p75 was significantly less than anti-trkA response, Constant phase model parameter of tissue elastance not significantly affected by any treatments or by increasing MCH dose, indicating development of significant regional ventilation inhomogeneity during bronchoconstriction. **Airway Pathology:** OVA-sensitized mice had small increases in intraepithelial mucus compared to vehicle-sensitized mice. DEP exposure did not enhance severity of OVA-induced airway pathology. Anti-p75 or anti-trkA administration did not influence airway morphology. **BAL Cells:** Vehicle-sensitized DEP-exposed mice had significantly enhanced macrophage numbers by 92% compared to air-exposed, vehicle-sensitized mice. Anti-p75 or Anti-trkA administration significantly suppressed DEP-induced macrophage increase to levels similar to air-exposed, vehicle-sensitized group. DEP co exposure significantly decreased number of macrophages in OVA-sensitized mice to control levels. Anti-trkA or anti-p75 had no effect in OVA-sensitized, DEP-exposed. Eosinophil number greater in OVA-sensitized DEP-exposed mice than in vehicle-sensitized air-exposed mice. No significant effects of DEP exposure on neutrophils from vehicle- or OVA-sensitized mice. **Cytokines:** IL4: OVA-sensitized DEP-exposed had five-fold increase over vehicle-sensitized, air-exposed mice and anti-trkA or anti-p75 significantly inhibited the DEP-induced increase. IL5, IL13: OVA-sensitized DEP-exposed had no significant change. Anti-p75 or anti-trkA administration had no significant effect. **Serum IgE**: OVA sensitized mice had a 10 fold increase in IgE levels for air and DEP exposed mice. Anti-p75, anti-trkA treatment did not cause significant effects on IgE levels.

Study	Pollutant	Exposure	Effects
Reference: Farraj et al. (2006, 088469) **Species:** Mouse **Gender:** Male **Strains:** C57/Bl6 **Age:** 6 wk	DEP: SRM 2975 collected from diesel-powered industrial forklift filter (NIST) OVA: Ovalbumin Anti-p75: Rabbit anti-mouse p75 neurotrophin receptor polyclonal antibody **Particle Size:** 1.47 (MMAD), 2.75 (GSD)	**Route:** Nose-only Inhalation **Dose/Concentration:** DEP: 0.87 mg/m^3 MCH: 0, 16, 32, 64 mg/ml OVA: 20 µg ip Anti-p75: 50 µl **Time to Analysis:** Day 0: OVA in gel vehicle, ip Day 14: anti-p75 exposure, intranasal instillation 1 h post anti-p75 exposure, OVA aerosol challenge for1 h 1 h post OVA challenge: DEP exposure for 5 h 48 h post DEP exposure: MCH challenge	**Airway Responsiveness:** No significant differences in average Penh values among any vehicle control groups. No significant differences in treatment groups in OVA-sensitized mice at baseline 0, 16, or 32 mg/mL of MCH. At 64 mg/mL MCH, OVA-sensitized, DEP-exposed mice had a 22% increase in Penh compared to vehicle mice, and a 68% increase compared to vehicle-sensitized, air-exposed mice. Instillation of anti-p75 inhibited the DEP induced increased Penh. **BALF Cells:** DEP exposure in vehicle-sensitized mice significantly increased macrophages by 161% compared to air-exposed, vehicle-sensitized mice, while OVA-sensitized mice had 69% increase. Anti-p75 administration significantly suppressed DEP-induced macrophage increase in vehicle-sensitized mice. No significant effects of DEP exposure or anti-p75 treatment in OVA-allergic mice. OVA-sensitized air-exposed mice had a several hundred fold increase in the number of eosinophils. No significant effects of DEP exposure or anti-p75 treatment on eosinophils from OVA-sensitized mice. OVA-exposure or DEP-exposure had no significant effects on neutrophil or lymphocyte number . **Cytokines:** No significant effects of DEP alone or with OVA on IL-4, IL-5, or IL-13. **Serum IgE:** OVA sensitization in the presence or absence of DEP or anti-p75 caused at least a 3 fold increase in IgE levels. No significant effects of DEP or anti-p75 treatment on IgE levels.
Reference: Finkelman et al. Group 2: daily ip injections of 2 mg of DEP **Dose/Concentration:** 2 mg **Time to Analysis:** 2-96 h	**Serum Cytokines:** Mice in group 1 demonstrated an increase in serum IL-6 production but no increase in IL-4 or IL-2 production. IFN-γ levels were decreased in group 2. TNF production was not affected. **Spleen Cytokines:** When injected before LPS, DEP had little effect on the LPS-induced TNF-α and IL-6 response, but resulted in a minor suppression of INF-γ and IL-10. DEP LPS-induced increase in INF-γ mRNA responses in spleen cells. DEP caused a dose related suppression of LPS stimulated INF-γ. DEP had little or no effect on the percentage of NK or NKT cells in the spleen and inhibited LPS-induced IFN-γ production by NK and NKT. DEP failed to inhibit the IFN-γ response by anti-CD3 mAb-activated NKT cells. Oxidant activity was not responsible for DEP inhibition of LPS-induced IFN-γ production.
Reference: Fujimaki and Kurokawa (2004, 096575) **Species:** Mouse **Gender:** Male **Strains:** BALB/c **Age:** 4 wk **Cell Types:** Cervical lymph-node (CLN) cells	DE ± particles: Comparison of exposure to DE including particles and exposure to particle-filtered DE DE: 12.09 ± 0.15 NO_X, 1.99 ± 0.02 NO_2, 10.02 ± 0.12 NO, 0.18 ± 0.002 SO_2 and 1769.2 ± 13.2 CO_2 (all in ppm). DE gas: 11.93 ± 0.13 NO_X, 2.93 ± 0.06 NO_2, 8.91 ± 0.09 NO, 0.11 ± 0.003 SO_2 and 1838.8 ± 15.3 CO_2 (all in ppm) **Particle Size:** 0.4 µm (MMAD)	**Route:** Whole-body Inhalation **Dose/Concentration:** Exposure to; 0, 1.0 mg/m^3 or 1.0 mg/m^3 DE gas only (0.04 mg/m^3 PM) **Time to Analysis:** Exposure for 12 h daily for 5 wk. Days 14 and 35 challenge with sugi basic protein (SBP), a cedar pollen allergen, intranasally. Evaluation is 24 and 48 h after final SBP injection.	**CLN Response:** Exposure to DE or DE gas did not affect B1 lymphocyte subpopulations of CLN. Culture supernatants of CLN cells from DE exposed/SBP immunized mice showed significant increase in MCP-1 at 24 and 48 h. Exposure to DE or DE gas significantly increased the amount of TARC and MIP-1α in CLN cells from SBP-immunized mice at 48 h.

Study	Pollutant	Exposure	Effects
Reference: Fujimaki et al. (2005, 156456) **Species:** Mouse **Gender:** Male **Strains:** C57BL/6 **Age:** 4 wk	DE generated by 4 cyl 2.74 l Isuzu diesel DE gas = DE filtered to remove particles Composition of Diesel Exhaust**:** DE DEP: 1.01 mg/m^3 1796 ppm CO_2 12.09 ppm NO_X 0.18 ppm SO_2 Composition of filtered DE Gas: DEP: 0.04 mg/m^3 1839ppm CO_2 11.93ppm NO_X 0.11 ppm SO_2 Sugi Basic Protein (SBP)- allergen **Particle Size:** 0.4 µm (average diameter)	**Route:** Whole-body Inhalation **Dose/Concentration:** 1.0 mg DEP/m^3 or 1.0 mg DEP/m^3 DE gas **Time to Analysis:** 12 h daily, 5 wk. All mice were injected IP with 100 µg SBP before exposure to gas or DE and again received 50 µg SBP intranasally on days 14 and 35. Evaluation is 1 day after final SBP-immunization (mice are euthanized and CLN and blood samples are collected)	**CLN:** Exposure to DE and gas led to a decrease in total number of CLN cells and percentage of CD4+ and TCR-B levels. Cell proliferation response to SBP was higher in gas-exposed mice than in the control group. The production of MCP-1 increased in CLN cells when stimulated with SBP (in vitro) but the difference was not significant at 24 and 48 h. SBP-stimulated cells in gas-exposed mice showed greatly enhanced MIP-1α production at 24 and 48 h. Exposure to gas increased the amount of TARC in the culture supernatants of CLN cells. **Plasma:** Exposure to DE or gas significantly decreased the anti-SBP IgG1 antibody titers and increased the anti-SBP IgG2a antibody titers in mouse plasma.

Exposure time was 12 h daily for 7 days/wk. Pregnant females were sacrificed 14 days postcoitum.	**mRNA Expression in Placentas**: In groups exposed to DE, the expression of CYP1A1 mRNA decreased to undetectable levels during placental absorption and INF-γ was increased. Levels of CYP1A1 mRNA in normal placentas from DE-exposed mice were unchanged. mRNA levels of inflammatory cytokines IL-2, IL-5, IL-12α, IL-12B and GM-CSF increased in placentas of mice exposed to DE.
Reference: Gao et al. (2004, 087950) **Species:** Human **Cell Line:** Lung fibroblasts infected with Mycoplasma fermentans	ROFA: collected near a power plant in FL burning low sulfur # 6 oil. (PM from Dusseldorf, volcanic ash for Mt. St. Helens, PM from Utah used to compare against ROFA in one experiment) $NiSO_4$, $CuSO_4$, $VOSO_4$, Na_3VO_4 **Particle Size:** NR	**Route:** Cell Culture; seeded into 6-well plates (3-4.5×10^5 cells/3 mL/well) or 24-well plates (0.6-1×10^5 cells/1.0 mL/well) **Dose/Concentration:** PM: 3, 10, 20, 40, 50 µg/ml Metallic salts: 2, 20, 200 µM **Time to Analysis:** 24, 48h	**Cytokines:** ROFA exposure in combination with Mycoplasma fermentans infection synergistically amplifies the induction of IL-6 production in human lung fibroblasts (HLF). PM from the other sources has little synergistic effect on IL-6 release. Exposing HLF cells to,M. fermentans derived macrophage activating lipopeptide-2 (MALP-2) and ROFA has the same synergistic effect as M. fermentans infection and ROFA. MALP-2 and ROFA extract have a similar synergistic effect that requires more time to appear. ROFA contains high levels of V, Ni, Fe and Cu. Exposure of HLF to $NiSO_4$ alone and $NiSO_4$ with MALP-2 produced 10 and 50 fold increases, respectively, in IL-6 production. Exposure of HLF to $CuSO_4$, $VOSO_4$ and Na_3VO_4, with and without the presence of MALP-2, did not produce as dramatic results as seen with Ni. The action of $NiSO_4$ and MALP-2 on IL-6 production was found to be dose dependent.

Study	Pollutant	Exposure	Effects
Reference: Gavett et al. (2003, 053153) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 7wk	$PM_{2.5}$ from the German cities of Hettstedt or Zerbst PM Composition: samples from Hettstedt have several-fold higher levels of Zn, Mg, Pb, Cu and Cd than samples from Zerbst. **Particle Size:** $PM_{2.5}$	**Route:** Oropharyngeal Aspirations **Dose/Concentration:** 50-100 µg **Time to Analysis:** Single, 18 h. Sensitization Model: Mice were exposed to 50 µg PM 2 h before being sensitized with 10 µg OVA, repeated two days later. On day 14 all mice were challenged with 20 µg OVA. Parameters measured on days 2 and 7 after final exposure to OVA. Challenge Model: Mice were sensitized IP with 20 µg OVA or adjuvant only. 14 days later mice were exposed to 100 µg $PM_{2.5}$ followed 2 h later by 20 µg OVA. Parameters measured on days 2 and 7 after final exposure to OVA.	**BAL Analysis**: Hettstedt PM significantly increased BAL protein and NAG levels. Zerbst PM did not. Mice exposed to Zerbst had lower levels of LDH than control groups. Hettstedt exposed mice had increased levels of IL-1B, IL-6 and MIP-2 in comparison to control and to mice exposed to Zerbst PM. $PM_{2.5}$ at a dose of 100 µg was not found to be toxic, therefore used for subsequent studies. **Airway Responsiveness (PenH)**: In allergic mice tested immediately after exposure, Hettstedt PM increased PenH 190% compared to baseline, Zerbst increased PenH by 120% and the Control increased by 44%.:.: Two days after OVA challenge, no differences in non-allergic mice from either group. In allergic mice, Hettstedt PM still caused a significant response to Mch responsiveness, Zerbst none. No effects on day seven. **IgE Levels**: Serum collected on day 2 showed antigen-specific IgE was increased by Hettstedt $PM_{2.5}$ in both the sensitization and challenge phases when compared to the control and exposure to Zerbst. Day 7 serum indicated no effect. **BALF Cells**: In non-allergic mice both Hettstedt and Zerbst PM increased neutrophil numbers (3-fold; not statistically significant) and in allergic mice, only Hettstedt PM significantly increased neutrophil count. Eosinophil numbers were increased only in allergic mice exposed to Hettstedt PM. Lymphocyte numbers were not different among groups. **BAL Injury Markers:** At 2 days after both Hettstedt and Zerbst PM administered in allergic mice caused significant increases in protein, LDH and NAG compared to the non-allergic groups. Both PMs caused an increase in LDH in allergic mice compared to the allergic control, but only Hettstedt caused an increase NAG in allergic mice compared to control. At 7 days no effect. **BAL Cytokines**: Allergic mice had increased levels of IL-4, IL-5 and IL-13 compared to non-allergic mice (at 2 days after). IL-5 was significantly increased by exposure to either PM in allergic mice compared to non-allergic mice. Exposure to either PM caused an increase in TNF-α and IFN-γ (by 6-8 fold) in allergic mice, there was also an increase in these inflammatory cytokines in the non-allergic group but was not statistically significant. No significant effects were observed in animals that underwent the sensitization protocol alone for any measurement or endpoint.
Reference: Gowdy et al. (2008, 097226) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** ~12-14 wk **Weight:** 17-20 g	DEP (30kW (40hp) 4-cylinder Deutz BF4M1008 diesel engine, steady state, 20% full load) (Low dose: 21% O_2, 0.4wt ratio OC/EC; High dose: 20.7% O_2, 0.4wt ratio OC/EC) (CO, NO_X, SO_2) **Particle Size:** Diameter: ~240 nm	**Route:** Inhalation **Dose/Concentration:** Low- 514 ± 3 µg/m^3, High-2026 ± 38 µg/m^3 **Time to Analysis:** 4 h/day, 1 or 5 days (consecutive). Necropsied immediately or 18 h postexposure.	**BAL Analysis:** Neutrophils and lung injury dose-dependently increased. ICAM-1 increased immediately after both exposures and after 18h postexposure in the low dose. **Cytokines:** After 1 day exposure, IFN-γ and TNF-α increased immediately at both doses and the high dose, respectively. Immediately after 5 days exposure TNF-α and IFN-γ increased at both concentrations and IL-6 increased at the low dose. At 18 h postexposure IL-6 and IFN-γ increased at both doses, TNF-α and IL-13 increased at the low dose, and MIP-2 dose-dependently increased. **CCSP, Surfactants:** CCSP decreased. SP-A and SP-D decreases were only significant after 5 days exposure, 18 h post-exposure.

Study	Pollutant	Exposure	Effects
Reference: Hamada et al. (2007, 091235) **Species:** Mouse **Gender:** Female (Pregnant close to partruition) **Strain:** BALB/c	ROFA (obtained from a precipitator until of a local power plant) Composition of ROFA (in µg/mL): 341.2 Ni, 323.4 V, 232.2 Zn, 18.3 Co, 15.8 Mn, 8.4 Ca, 6.7 Cu, 6.1 Sr, 5.0 mg, 0.9 Sb, and 0.6 Cd. **Particle Size:** NR	**Route:** Nebulized ROFA leachate **Dose/Concentration:** 50 mg/mL dilution **Time to Analysis:** Pregnant mice exposed to nebulized ROFA leachate for 30 min/day at days 14, 16 and 18 of pregnancy. Newborns received a single injection (ip) of OVA (5 µg)+ alum (1mg) at day 0 followed by exposure to: 1. aerosolized OVA days 12, 13 and 14 (2-wk old protocol) OR 2. aerosolized OVA days 32, 33 and 34 (5 wk old protocol) Analysis 48 h after final allergen exposure	**Susceptibility to Asthma**: Exposure of mother to PBS aerosols during pregnancy did not result in prominent asthma features in young. The offspring of the ROFA mothers revealed increasing AHR and elevated numbers of eosinophils in the BAL fluid. Similar results were seen in both the 2-wk and 5-wk old groups. **IgE Levels**: Histopathology revealed prominent inflammation in the lungs of the ROFA neonates and increased allergen-specific IgE and IgG1 levels in the 5-wk group. **Maternal Influence**: Breast milk was not shown to be responsible for the increased susceptibility to allergy seen in offspring. **IL-4 and IFN-γ**: IL-4 and IFN-γ levels in maternal mice showed no difference between PBS exposed or ROFA exposed mice. Cultured spleen cells from mice born of ROFA-exposed mothers showed either increased or similar levels of IL-4 and decreased production of IFN-γ causing an increase in the ratio of IL-4/IFN-γ indicating greater susceptibility to develop Th2-allergic response. **Eosinophils:** Exposure of mothers to Ni levels similar to those found in ROFA had no appreciable effect on BAL eosinophil.
Reference: Hao et al. (2003, 096565) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 6-7 wk	DEP (4-cylinder diesel engine under a 10-torque load) **Particle Size:** NR	**Route:** Nebulization **Dose/Concentration:** 2 mg DEP m^3 **Time to Analysis:** Mild Sensitization- Mice receive IP OVA alum and are challenge with aerosolized OVA with and without DEPs. Mice sacrificed d19. Postchallenge Model- DEPs are delivered to mice sensitized by IP OVA and alum. Mice sacrificed d23. Transgenic Mice: Mice exposed to nebulized saline or DEPs for 1 h daily for 3 days. Mice sacrificed day 5.	**Mild Sensitization:** Exposure of previously OVA sensitized mice to aerosolized DEP and OVA did not affect OVA-specific IgE production, BAL eosinophilia or methacholine-induced AHR. Aerosolized particles induced inflammation and increased MBP deposition and MBP positive eosinophils in the mucosa. **IL-5 Transgenic:** Exposure to aerosolized DEP did not change BAL cytokine levels, but did increase AHR and BAL cell count. **Classic Sensitization, Post-Challenge:** Did not lead to a discernable increase in OVA-induced AHR. DEP treatment was associated with increased airway inflammation and mucin production in larger and intermediary airways.
Reference: Harkema et al. (2004, 056842) **Species:** Rat **Gender:** Male **Strain:** F344, BN **Age:** 10-12 wk **Weight:** NR	CAPs (Detroit; July-Sept. 2000; Harvard Ambient Fine Particle Concentrator) **Particle Size:** 2.5 µm (diameter)	**Route:** Inhalation; IT Instillation. **Dose/Concentration:** 4 day concentration: 676 ± 288 µg/m^3, 5 day concentration: 313 ± 119 µg/m^3, July concentration: 16-185 µg/m^3, September concentration: 81-755 µg/m^3; IT Instillation- 200 µL (soluble and insoluble) **Time to Analysis:** 10 h/day 1, 4, 5 day (consecutive); F344 rats sensitized to endotoxin, BN rats to OVA. Both groups killed 24 h post-exposure.	The retention of PM in the airways was enhanced by allergic sensitization. Recovery of anthropogenic trace elements was greatest for CAPs-exposed rats. Temporal increases in these elements were associated with eosinophil influx, BAL protein content and increased airway mucosubstances. A mild pulmonary neutrophilic inflammation was observed in rats instilled with the insoluble fraction but instillation of total, soluble or insoluble $PM_{2.5}$ in allergic rats did not result in differential effects.

Study	Pollutant	Exposure	Effects
Reference: Harrod et al. (2003, 097046) **Species:** Mouse **Gender:** NR **Strains:** C57BL/6 **Age:** 8-10 wk	DEE: Diesel Engine Emissions generated from a 5.9-liter turbo diesel engine fueled by Number 2 fuel. DEE Composition: NO_X: 2.0-43.3 ppm CO: 0.94-29.0 ppm SO_2: 8.3-364.9 ppb **Particle Size:** 0.1-0.2 µm (MMAD)	**Route:** Whole-body Inhalation RSV: IT administration **Dose/Concentration:** DEE: 38.8 µg/m^3 (low level) or 10027 µg/m^3 (high level) RSV: 100 µl **Time to Analysis:** 6 h/day, 7 days After the final 6 h exposure period mice were infected with RSV. Parameters measured 4 days post infection	**Viral Gene Expression:** For air+RSV, RSV-F gene expression was not apparent but RSV-G gene expression was detectable at very low levels. In DEE+RSV (for high and low levels), RSV-F and -G were markedly elevated. ß-Actin mRNA levels not changed in DEE-exposed compared to air-treated. DEE+RSV for high and low levels show 10- to 20- fold induction of RSV-G mRNA levels as compared to air+RSV. **BALF Cells:** Uninfected low-level DEE did not induce statistically significant increase in cell numbers as compared to air+RSV. High level DEE+RSV caused increase as compared to air+RSV. Uninfected high-level DEE had increase as compared to uninfected air group. For all groups, alveolar macrophages were predominant cell type and no substantial changes in infiltrating cell populations by exposure to DEE were noted. **Lung Inflammation & Airway Epithelial Morphology**: Lung sections from air- or DEE-exposed, uninfected did not exhibit any observable change. Low level DEE + RSV had increased inflammatory cell infiltration in peribronchial regions and loss of normal cuboidal appearance of Clara cells as compared to air+RSV. High level DEE+RSV had more apparent lung-inflammation, especially surrounding bronchi and bronchioles, and increased appearance of pseudo-stratified, columnar epithelial cell morphology and apparent airway epithelial cell sloughing as compared to low level DEE+RSV, indicating dose-related increase in lung histopathology to RSV infection by prior DEE exposure. **Cytokines:** TNF-α and IFN-γ were significantly increased in RSV-infected mice exposed to low or high level DEE and not increased in RSV-infected mice exposed to air. TNF-α levels elevated to similar levels for low and high level DEE+RSV. IFN-γ exhibited more dose-related increase with higher levels in high level DEE+RSV versus low level DEE+RSV. **Mucous Cell Metaplasia:** DEE exposure in uninfected was not altered. Mucous metaplasia was increased in epithelium of RSV-infected mice when exposed to DEE in a dose-dependent manner. Following high level DEE+RSV, mucous staining of airway epithelial cells in more distal airways was occasionally observed. **CCSP Production in Airway Epithelium:** DEE alone did not have an effect CCSP-producing cells, or Clara cells, decreased in Low DEE + RSV and further decreased in high level DEE+RSV in large and terminal airways. **Surfactant Protein B:** proSP-B staining post RSV alone shows now discernible decrease when compared to uninfected. Staining levels in alveolar lung regions decreased when exposed to low level DEE+RSV, and further decreased in high level DEE+ RSV. Staining in airway epithelium following high level DEE+RSV diminished when compared to RSV alone or low level DEE+RSV. **SP-A:** In alveolar type II cells and airway epithelial cells for untreated and air +RSV, no discernible changes in levels. Prior exposure to low or high level DEE decreased SP-A staining in alveolar type II cells and airways epithelial cells during RSV infection.

Study	Pollutant	Exposure	Effects
Reference: Harrod et al. (2005, 088144) **Species:** Mouse **Gender:** Male **Strain:** C57B1/6 **Age:** 10-12 wk **Weight:** NR	DEE (2 2000 model 5.9-1 Cummins ISB turbo diesel engines, No. 2 certification diesel fuel) **Particle Size:** NR	**Route:** Inhalation **Dose/Concentration:** Low- 30 µg/m^3 PM, Mid-Low- 100 µg/m^3 PM, Mid-High- 300 µg/m^3 PM, High- 1000 µg/m^3 PM **Time to Analysis:** 6 h/d, 7 days/wk, 1 wk or 6 mo. 1 wk exposure repeated on separate occasion. Immediately after exposure, mice anesthetized, IT instilled with Pseudomonas aeruginosa.	**Bacterial Clearance:** Lung bacterial clearance was decreased at all levels after 1wk exposure and was concentration-dependent 18h postinfection. Bacterial clearance was not affected at 6m and bacterial counts were higher. **Inflammation, Particle Deposition:** Lung inflammation and histopathology were increased in all exposure groups postinfection. All exposure groups possessed particle-laden macrophages. Higher doses had a concentration-dependent increase. **Ciliated, Clara Cells, TTF-1:** Generally, ciliated cells decreased with exposure dose, were more discernible in inflamed airways, and higher doses caused effects in small distal airways. Clara cells decreased equally at all exposures and were most notable in the distal airway epithelium. TTF-1 decreased postinfection.
Reference: Heidenfelder et al. (2009, 190026) **Species:** Rat **Gender:** Male **Strain:** Brown-Norway **Age:** 10-12 wk **Weight:** NR	CAPs (Grand Rapids, MI; July) **Particle Size:** Diameter: 0.1-2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** CAPs: 493 ± 391 µg/m^3; OC: 244 ± 144 µg/m^3, EC: 10 ± 4 µg/m^3, Sulfate: 79 ± 131 µg/m^3, Nitrate: 39 ± 67 µg/m^3, Ammonium: 39 ± 59 µg/m^3; Urban dust (Fe, Al, Ca, Si): 18 ± 6 µg/m^3 **Time to Analysis:** Sensitized to OVA 3 day. Challenged with OVA or saline 2wk later for 3 day. Exposed to CAPs 8h/d, 13d. OVA or saline challenge 9 day after first challenge. Sacrificed 24 h after last CAPs exposure.	CAPs enhanced the effects of OVA by causing differential expression in genes primarily involved in inflammation and airway remodeling. CAPs exposure alone had no effect on gene expression. CAPs+OVA also increased IgE, mucin glycoprotein, and BALF total protein, and caused a more severe bronchopneumonia, increased mucus cell metaplasia/hyperplasia and mucosubstances.
Reference: Hiramatsu et al. (2003, 155846) **Species:** Mouse **Gender:** Female **Strains:** BALB/c and C57BL/6 **Age:** 8 wk **Weight:** 17-22 g	DE -DE (generated by diesel engine and diluted with filtered clean air) **Particle Size:** NR	**Route:** Inhalation **Dose/Concentration:** Low -0.1 mg/m^3 High - 3 mg/m^3 **Time to Analysis:** 7 h/day, 5 days/wk, 1 or 3 mo	**Lung Histopathology:** DEP-laden macrophages accumulated in the alveoli and peribronchial tissues in a dose- and duration-dependent manner in both strains. Lymphocytes and neutrophils increased in both strains, but were greatest in the BALB/c mice. **BALF and Mac-1 Positive Cells:** BALT formation in DEP-laden AMs was seen at the high dose group and was greater in the BALB/c mice. Mac-1 positive cells, a marker for phagocytic activation of the AMs, was observed in the high dose groups of both strains at 1 and 3 mo, and in the low dose group at 1 mo. in BALB/c mice. **Cytokine and iNOS mRNA expression:**1 month of exposure increased TNF-α, IL-12p40, IL-4 and IL-10 mRNA in a dose-dependent manner. IL-1B and iNOS decreased in a dose-dependent manner. IFN-γ mRNA expression increased in BALB/c mice and decreased in C57BL/6 mice. Similar results were seen at 3 mo, except IL-4 and IFN-γ mRNA expression decreased in the BALB/c mice. In C57BL/6 mice, IL-4 and IL-10 mRNA increased at the low dose but decreased at the high dose. NF-κB activation occurred after 1 wk and 1 month DE exposure and was more prevalent in BALB/c mice.

Study	Pollutant	Exposure	Effects
Reference: Hiramatsu, (2005, 088285) **Species:** Mouse **Gender:** Female **Strains:** BALB/c **Age:** 8 wk **Weight:** 17-22 g	DE (generated by diesel engine and diluted with filtered clean air.) Mycobacterial Infection -M.tuberculosis (ATCC35812) Kurono strain **Particle Size:** NR	**Route:** Inhalation **Dose/Concentration:** Low - 0.1 mg/m^3 High - 3 mg/m^3 Mycobaterial infection: 5 mL (nebulized) of a 106 colony-forming units (CFU) suspension **Time to Analysis:** 7 h/day, 5 day/wk, 1, 2 or 6 mo. Subset infected on last day of DE exposure. CFU evaluation 7 wk postinfection.	**Histopathological Observations:** DEP-laden AMs and DEPs in the alveoli and peribronchial tissues increased in a time-dependent manner. DE-exposed mice had a greater number of mycobacterial lesions, which were disseminated. Lesions in the control mice had clear borders and consisted of epithelial cells and lymphocytes. Tubercle bacilli and DEPs coexisted in AMs. BALT was seen around DEPs in the 2 and 6-month exposure groups. Inflammation cells increased in a time-dependent manner with respect to DE exposure. **Granulomatous Lesions in Lungs:** 6-month DE-exposed mice had a significantly higher amount of gross lesions than the 6-month control mice. **Mycobacterial Burden:** CFU in lungs were increased in DE-exposed animals but only the 6 month exposure resulted in statistically significant increases (a ~4-fold increase over control). CFU in spleen were not significantly altered by DE exposure. **Cytokines and iNOS mRNA Expression:** Infected DE-exposed mice had time-dependent increases of TNF-α, IL-1B, IL-12p40, IFN-γ and iNOS mRNAs compared to the infected control mice. IL-12 mRNA expression decreased in infected 6-month DE-exposed mice.
Reference: Ichinose, T. et al. (2003, 041525) **Species:** Mouse **Gender:** NR **Strains:** BALB/cAnN, ICR, C3H/HeN **Age:** 6 wk **Weight:** NR	DE: DE generated by 3059cc 4-cylinder diesel engine Der f: Crude extract of D. farinae **Particle Size:** 0.4 µm (MMAD)	**Route:** Inhalation **Dose/Concentration:** 1. Air 2. DE only: 3.0 mg/m^3 3. Air + Der f: 1 mg Der f 4. DE 3.0 mg/m^3 + 1 mg Der f **Time to Analysis:** DE: 12 h/day, 7 days/wk, 8 wk Der f: 2 wk intervals, 6 wk Analyzed 3 days after last instillation	**Light Microscopic Observations:** DE exposure caused the proliferation of nonciliated cells and epithelial cell hypertrophy. Soot-containing macrophages were found in the alveolar tissue spaces. Accumulated lymphocytes were present in the peribronchiolar lymphoid tissue. Inflammatory cells and soot-containing macrophages were found in the submucosal layer and the vessel interstitium of mice treated with DE+Der f in all strains. DE+Der f treated C3H/He mice had desquamated goblet cells. **Eosinophil Infiltration:** DE treated C3H/He mice had a slight eosinophil infiltration in the submucosal layer. DE+Der f treated mice in all strains had a slight to moderate eosinophil infiltration. **Lymphocyte Accumulation:** Lymphocytes significantly increased in all strains under the DE treatment as compared to the air+saline treatment, and further increased under the DE+Der f treatment. **Goblet Cell Proliferation:** Little proliferation was seen in all strains under the DE treatment. DE+Der f caused a significant increase in proliferation compared to air+Der f in ICR mice, but a significant decrease in C3H/He mice. **Local Cytokine and Chemokine Expression in Lung Tissue Supernatant:** DE+saline significantly increased MIP-1α in all strains. MCP-1 also increased but not significantly. DE+Der f increased IL-5, RANTES, eotaxin, MCP-1 and MIP-1α in all strains as compared with air+saline and air+Der f. IL-5 decreased in C3H/He mice treated with DE+Der f compared to air+Der f. IL-3 decreased in ICR and C3H/He mice compared to air+saline. **Der f-specific Immunoglobulin Production in Plasma:** Increased production of IgG1 was statistically significant in ICR and C3H/He mice treated with DE+Der f as compared to air+Der f. IgE was low in all strains.

Reference: Ichinose et al. (2004, 180367) **Species:** Mouse **Gender:** NR **Strains:** BALB/c, ICR and C3H/He **Age:** 5 wk **Weight:** NR	DEP: 2740cc 4-cylinder engine D. farinae: crude extract **Particle Size:** 0.4 µm (MMAD)	**Route:** IT Instillation **Dose/Concentration:** 1. D. farinae: 1 µm in PBS 2. D. farinae + DEP: 1 µg in PBS + 50 µg mg DEP **Time to Analysis:** 4 times at 2 wk intervals. Mice examined 3 wk after last instillation	**Histological Changes:** Mice in all three strains treated with DEP+D. farinae had a significant recruitment of eosinophils, more proliferation of goblet cells, and more eotaxin positive macrophages in the alveoli than mice treated with D. farinae alone. **Local Cytokine Expression in Lung Tissue Supernatant:** DEP+D. farinae induced significant elevation of IL-5 in ICR and C3H/He mice as compared to D. farinae alone. Production levels of IL-4 and RANTES did not correlate with the manifestations of allergic airway inflammation induced by the D. farinae treatment with or without DEP. **Cytokine Expression in Plasma:** IL-5 in C3H/He mice treated with DEP+D. farinae was significantly higher than D. farinae alone. RANTES was unaffected by the DEP treatment in all strains. **D. farinae-specific Immunoglobulin Production in Plasma:** The adjuvant effect of DEP on IgG1 production was observed in all three strains, with C3H/H3 being statistically significant. The production levels of IgG1 correlated with the manifestations of eosinophilic airway inflammation by both treatments. No adjuvant effect on IgE production was observed.
Reference: Inoue et al. (2007, 096724) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6 wk **Weight:** 29-33 g	PM-OC: Urban PM, collected for 1 month during early summer, 2001 in Urawa city Saitama, Japan LPS **Particle Size:** <2.0 µm	**Route:** IT Instillation **Dose/Concentration:** Vehicle group: PBS PM-OC group: 4 mg/kg of PM-OC LPS group: 2.5 mg/kg of LPS PM-OC+LPS group: combined administration of PM-OC +LPS **Time to Analysis:** Single, 24 h	**Effects of PM-OC on LPS Related Lung Inflammation**: PM-OC alone did not significantly increase the infiltration of neutrophils, but LPS challenge showed a marked increase in the number of neutrophils compared with vehicle. Administration of LPS combined with PM-OC significantly increased the infiltration of neutrophils compared with LPS administration alone. **Effects of PM-OC on Histological Changes in the Lung:** Combined treatment with PM-OC and LPS resulted in enhanced neutrophilic inflammation. **Effects of PM-OC on Pulmonary Edema Related to LPS**: LPS group compared with vehicle group had a significant increase in lung water. The combined administration of PM-OC and LPS resulted in further increase in the lung water compared with LPS administration alone, however it was not statistically significant. **Effects of PM-OC on Protein Expression IL-1B, MIP-1α, MCP-1 and KC:** The concentrations of these molecules were below the detection limits in the PM-OC group. LPS treatment significantly increased the protein levels of these molecules compared with the vehicle treatment. In the PM-OC + LPS group all concentrations, particularly KC, were smaller than in the LPS group.

COX-2 in the DEP-OC + LPS decreased when compared to the LPS only group. **Pulmonary Edema:** Washed DEP + LPS group showed a synergistic enhancement of pulmonary edema and local expression of proinflammatory chemokines (MCP-1, MIP-1α, KC, IL-1B).
Reference: Inoue et al. (2006, 096720) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6-7 wk **Weight:** 29-33 g	Carbon black (PrinteX 90; PrinteX 25; Degussa, Dusseldorf, Germany) **Particle Size:** 14 nm - 300 m^2/g 56 nm - 45 m^2/g	**Route:** IT instillation **Dose/Concentration:** Vehicle group: PBS Ovalbumin (OVA) group: 1mg OVA; Nanoparticle groups: 50 mg carbon black nanoparticles (14 nm or 56 nm);;OVA + nanoparticle group: combined administration of nanoparticles and OVA **Time to Analysis:** Vehicle group - weekly for 6wk OVA group - biweekly for 6 wk Nanoparticle groups - weekly for 6 wk OVA+Nanoparticle group (same protocol as OVA and Nanoparticle) studied 24 h after last administration	**Nanoparticles:** Exposure to carbon nanoparticles resulted in the lung expression of TARC, GM-CSF and MIP-1α. The levels were higher in the 14 nm group compared to the 56 nm group. **OVA:** In the presence of OVA, nanoparticles enhanced levels of TARC, GM-CSF, MIP-1α, IL-2 and IL-10, with the effects seen more prominently in the 14 nm particles + OVA group.

Study	Pollutant	Exposure	Effects
Reference: Inoue et al. (2005, 088625) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6-7wk **Weight:** 29-33 g	Carbon black (PrinteX 90; PrinteX 25; Degussa, Dusseldorf, Germany) **Particle Size:** 14 nm - 300 m^2/g 56 nm - 45 m^2/g	**Route:** IT Instillation **Dose/Concentration:** Vehicle group: PBS; Ovalbumin (OVA) group: 1mg OVA; Nanoparticle groups: 50mg carbon black nanoparticles (14nm or 56 nm); OVA + nanoparticle group: combined administration of nanoparticles and OVA **Time to Analysis:** Vehicle group - weekly for 6 wk OVA group - biweekly for 6 wk Nanoparticle groups - weekly for 6 wk OVA+Nanoparticle group: same protocol as OVA and Nanoparticle studied 24 h after last administration	**Nanoparticles + OVA:** Nanoparticles given with OVA enhanced airway inflammation, characterized by increased eosinophils, neutrophils, mononuclear cells and goblet cells. In addition, nanoparticles + OVA significantly increased local expression of IL-4, IL-5, eotaxin, IL-13, RANTES, MCP-1 and IL-6. The formation of 8-OHdG was enhanced by nanoparticles + OVA. **14 nm Nanoparticles:** All these effects were more prominent when 14 nm nanoparticles were used. The 14 nm nanoparticle + OVA group significantly raised levels of total IgE and antigen specific production of IgG1 and IgE.
Reference: Inoue et al. (2006, 190142) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6 wk **Weight:** 29-33 g	Whole DE (generated by 4-cylinder, 3.059l, Isuzu diesel engine, Isuzu automobile, Tokyo, Japan) LPS **Particle Size:** 110 nm (peak particle size)	**Route:** Whole-body Inhalation **Dose/Concentration:** 0.3 mgsoot/m^3 1.0 mgsoot/m^3 3.0 mg soot/m^3 LPS: 125 mg/kg **Time to Analysis:** LPS prior to 12 h exposure to exhaust	BAL fluid, total cells, neutrophils, protein and gene levels (MCP-1 and KC) decreased compared to control with LPS, but were smaller with LPS + DE. Results are suggestive that short-term exposure to DE does not exacerbate LPS-related lung inflammation.
Reference: Inoue et al. (2007, 096702) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6 wk **Weight:** 29-33 g **Cell Type** Splenocytes	DEPs [4JB-1 type light-duty, four-cylinder, 2.74 liter Isuzu diesel engine (Isuzu Automobile Co., Tokyo Japan)] LPS **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture (Splenocytes resuspended to cell density of 1×10^6/mL and 1000 mL applied into each of 12-well plate) **Dose/Concentration:** DEP: 100 mg/mL; LPS: 1 mg/mL; LPS(1mg/mL) + DEP (1, 10 or 100 mg/mL) **Time to Analysis:** 72 h	**Cell viability:** No effect. **Mononuclear cell response:** Incubation with DEP alone inhibited basal cytokine production. LPS significantly increased protein levels of IFN-γ, IL-2, and IL-10 compared to control. DEP suppressed the LPS-enhanced protein levels in a dose-dependent manner and moderately elevated the IL-13 level.
Reference: Inoue et al. (2007, 198885) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6-7 wk **Weight:** 20-30 g	Carbon nanoparticles (PrinteX 90, PrinteX 25; Dusseldorf, Germany) OVA **Particle Size:** CB14 = 14 nm, CB56 = 56 nm	**Route:** IT Instillation **Dose/Concentration:** 50 µg and/or 1 µg OVA in PBS **Time to Analysis:** 1×/wk for 6 wk; sacrifice 24 h after last exposure	**Lung Responsiveness:** Respiratory system resistance, Newtonian resistance and tissue dampening were significantly higher in the nanoparticle + OVA groups. Elastance and tissue elastance were higher in these groups but not significantly so. Compliance was significantly lower in the nanoparticle + OVA groups compared to the control. **Lung mRNA Level for Muc5ac**: Levels were significantly higher in nanoparticle + OVA groups compared to the control.
Reference: Inoue et. al. (2007, 096692) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 6-7 wk **Weight:** 29-34 g	DEP-OC collected from 4JB1 type, light duty, 4 cylinder, 2.74 liter Isuzu diesel engine, Isuzu Automobile Company, Tokyo, Japan) OVA **Particle Size:** 0.4 µm	**Route:** IT Instillation **Dose/Concentration:** 50 µg and/or 1 µg OVA in PBS **Time to Analysis:** DEP or DEP-OC w/ or w/o OVA initially; OVA or vehicle every 2 wk for 6 wk; DEP components or vehicle 1×/wk for 6 wk; sacrifice 24 h after last instillation	Total respiratory system resistance, elastance, Newtonian resistance, tissue damping, tissue elastance displayed general positive trends and were significantly higher in OVA and OVA + DEP-OC groups. Compliance displayed a general negative trend and was significantly lower in the washed DEP + OVA group.

(2006, 088391) **Species:** Rat **Cell Line:** L2 cells of alveolar epithelial cell type II origin	DEP - generated from 2982-cc common rail direct injection diesel engine with oxidation catalyst and exhaust gas recirculation system. **Particle Size:** $PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** 1×10^6 1,10 or 30 mg/mL **Time to Analysis:** 3 h	**ICAM-1 and LDL Receptor mRNA**: Up-regulation in a dose-dependent manner. Statistically significant at 30 mg/mL compared to control. **HO-1 and PAF Receptor mRNA**: Up-regulation in dose-dependent manner and statistically significant at all doses compared to control. **Correlation Between HO-1 and ICAM-1, LDL, and PAF:** Significant correlation between HO-1 and each of these.
Reference: Jang et al. (2005, 155313) **Species:** Mouse **Gender:** Female **Strains:** BALB/c **Age:** 5-6 wk	DEP -generated from 4JB1 type, light duty, four-cylinder diesel engine (Isuzu Automobile, Co, Tokyo, Japan) O_3 - (generated with Sander Model 50 ozonizers, Sander, Eltze Germany) OVA **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** DEP: 2,000 µg/µL (sic) O_3: 2 ppm (avg 1.98 ± 0.08 ppm) OVA sensitization: 10 mg **Time to Analysis:** OVA sensitization, DEP, O_3 and OVA Challenge on d21- 23 Exposed to O_3 for 3 h and DEP for 1 h AH and BAL measured 1 day after last challenge	**Airway Responsiveness**: OVA + O_3 + DEP exposure group had significantly higher methacholine-induce Penh than sham group or OVA group. **Total cells, proportion of eosinophils and neutrophils**: The OVA + O_3 + DEP group was significantly higher than OVA group and OVA+ O_3 group. **IL-4:** OVA + O_3, OVA + DEP and OVA + O_3 + DEP IL-4 level increased compare to OVA group. **IFN-γ:** Levels significantly decreased in OVA + DEP and OVA + O_3 + DEP compared to OVA + O_3.
Reference: Jaspers et al. (2005, 088115) **Species:** Human **Cell Lines:** A549 cells, primary human bronchial and nasal epithelial cells	DEas: aqueous-trapped solution of DE (emissions from Caterpillar diesel engine, model 3304) Influenza: A/Bangkok/1/79 (H3N2 serotype) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Influenza: 3×10^5 cells infected with 320 hemagglutination units (HAU) DEas**:** For A549 cells: 6.25, 12.5, 25 µg/cm^2. For bronchial and nasal cells: 22 or 44 µg/cm^2. **Time to Analysis:** 2 h incubation with DEas then virus added. HA RNA levels analyzed at 0, 15, 30, 60 or 120 min post infection. IFN and MxA responses: analyzed 24 h post infection. Fluorescence: some cells treated with GSH-ET 30 min before DEas exposure. Measured 2 h post-influenza infection.	**A549 Cells Increased Susceptibility:** DEas enhances HA RNA levels in A549 cells in a dose-dependent manner. 25 µg/cm^2 significantly enhanced levels in A549 cells compared to the influenza-infected controls. Viral protein levels were increased in A549 cells. Exposure to DEas increased the number of influenza-infected epithelial cells in A549 cells. **Human Nasal and Bronchial Cells Susceptibility:** Exposure to DEas increased HA RNA levels in the nasal and bronchial cells. Statistically significant at 22 µg/cm^2 for nasal cells and approaching significance at 44 µg/cm^2 for bronchial cells. Exposure of both types to 44 µg/cm^2 enhanced viral protein levels. **Influenza Induced IFN Response in A549:** Exposure to DEas does not suppress but enhances IFN-ß mRNA levels. Treatment enhanced influenza-induced nuclear levels of both phospho-STAT-1 and ISFG3g. ISRE-promoter activity was enhanced, but not significantly. Treatment enhanced myxovirus resistance protein (MxA) mRNA levels. This data suggest that DEas exposure enhances influenza virus replication without suppressing production of IFN-ß or IFN-ß-inducible genes. **Influenza Induced IFN Response in Human Nasal and Bronchial Cells:** Exposure to DEas increased IFN-ß and MxA levels. **Oxidative Stress in A549:** DEas exposure dose-dependently increases oxidative stress in A549 cells within 2-h post-exposure. Add the antioxidant GSH-ET and it reverses the effect. Pretreatment with GSH-ET A549 cells reversed the effects of DEas on the number of influenza-infected cells, and reduced HA RNA levels. **Oxidative Stress in Human Bronchial Cells:** The results were the same as A549 cells pretreated with GSH-ET. Or Pretreatment with GSH-ET also reversed effects of DEas on HA RNA levels.

Study	Pollutant	Exposure	Effects
Reference: Kaan and Hegele (2003, 095753) **Species:** Guinea pig **Gender:** Female **Strain:** Cam Hartley **Age:** 22-29 days **Weight:** 250-300 g **Cell Types:** AM	PM_{10} - EHC-93 obtained (Environmental Health Canada, Ottawa, ON, Canada) RSV - Human RSV (long strain/lot18D) (American Tissue Culture Collection, Bethesda, MD) **Particle Size:** PM_{10} (0.35 µm MMAD)	**Route:** Cell Culture **Dose/Concentration:** PM_{10}: 500 µl/well (100 µg/ml MEM) RSV exposure:: 1 ml/well (6×10^6 pfu/ml MEM) Groups: PM_{10}+RSV RSV+PM_{10} RSV only PM_{10} only negative control **Time to Analysis:** PM_{10} - 60 min; RSV - 90 min Parameters measured 24 h post treatment	**Interaction on Phagocytic Ability of AM:** Not affected by sequential exposure to RSV and PM_{10}. More than 95% of AM exposed to PM_{10} engulfed PM. AM exposed to PM_{10} showed significant increase in mean side scatter in comparison to negative control and RSV-infected AM. No significant difference between AM exposed only to PM_{10} and AM exposed to both agents. No significant side mean side scatter difference between AM exposed to PM only and to both agents. **Interaction on RSV Immunopositivity:** PM_{10} exposure inhibits. All RSV-treated groups showed significantly greater proportion of RSV-immunopositive cells compared with negative control. PM_{10}+RSV showed significantly smaller proportion of RSV-immunopositive cells compared with RSV group. RSV+PM_{10} group similar to RSV group. Proportion of RSV-immunopositive AM was influenced by the sequence of exposure to RSV and PM_{10}. **Interaction on RSV Replication:** PM exposure suppressed RSV replication. AM exposed to both agents produced 3 to 9 fold less RSV progeny compared with RSV alone group. Quantity of RSV progency was not significantly affected by the sequence of exposure RSV and PM_{10}. Negative control and PM_{10} only did not propagate progeny. **Interaction of RSV Yield:** RSV alone group produced the highest RSV yield, those exposed to both agents, independent of sequence, showed a 5-fold decrease. **Cytokine production:** RSV infection stimulated all three cytokines measure (IL-6, IL-8 and TNF-α) compared to negative control. IL-6: PM_{10} significantly reduced RSV-induced IL-6 production. IL-6 was affected by the sequence of exposure to PM_{10} and RSV (PM_{10}+RSV vs. RSV+ PM_{10}). IL-8: PM_{10} significantly decreases RSV-induced IL-8 production and baseline. No affect on sequence of exposure. TNF-α: production was increased when exposed to RSV, PM_{10} or a combination of both agents. No differences among treatments.
Reference: Kleinman et al. (2005, 087880) **Species:** Mouse **Gender:** Male **Strains:** BALB/c **Age:** 8-19 wk **Weight:** NR	CAPS: fine (F) and ultrafine (UF) using VACES system; performed a 2 sites in Los Angeles, CA, one 50-m downwind and another 150-m downwind from a complex of three roadways, State Road CA60, Interstate 10, and Interstate 5 F CAPS in 2001 and 2002, UF CAPS in 2002 only OVA: Ovalbumin **Particle Size:** UF: dp ≤ 150 nm F: dp ≤ 2.5 µm	**Route:** Whole-body Inhalation OVA sensitization: nasal instillation OVA challenge: inhalation **Dose/Concentration:** UF at 50 m: 433 µg/m^3 -UF at 150 m: 283 µg/m^3 F at 50 m or 150 m: average 400 µg /m^3 OVA sensitization: 50 µg/5 µl OVA challenge: 30 mg/m^3 **Time to Analysis:** CAPS: 4 h/day, 5 days/wk for 2 wk Sensitization: On morning of each exposure 1st Challenge: week after 10 days of treatment 2nd Challenge: one week following 1st challenge Sacrificed: 24 h after 2nd challenge	There were significantly higher concentrations of IL-5, IgE, IgG1 and eosinophils in mice exposed to either CAPS compared to air. Mice exposed to CAPS at 50-m downwind showed higher levels of IL-5, IgG1, and eosinophils than those exposed to CAPS 150-m downwind.

Fall 2001-summer 2004 OVA **Particle Size:** F: $PM_{2.5}$; UF: PM0.15	**Route:** Whole-body Chamber **Dose/Concentration:** 50 m - F: 394 ± 94 µg/m^3 50 m - UF: 297 ± 189 µg/m^3 150 m - F: 387 ± 68 µg/m^3 150 m - UF: 213 ± 95 µg/m^3 OVA - 50 mg in 5 mL saline **Time to Analysis:** 3, 4 h/day, 5 days/wk, 2wk OVA the morning of each exposure	**50m Site**: higher levels and statistically significant concentration curves of IL-5 and IgG1 in F-CAP mice at the 50 m site. **150m Site:** in no cases were responses greater than the 50m or control groups. **F vs. UF:** The study was not able to differentiate between the effects of F PM and UF PM exposures.
Reference: Klein-Patel et al. (2006, 097092) **Species:** Cattle and Human **Cell Types** Bovine tracheal epithelial cells (BTE) and A549	ROFA V_2O_5, $VOSO_4$, SiO_2 TiO_2, $Fe_2(SO_4)_3$, $NiSO_4$, LPS **Particle Size:** 1.95 µm (MMAD)	**Route:** Cell Culture **Dose/Concentration:** ROFA: 0, 2.5, 5, 10, 15, 20 µg/cm^2 LPS: 100 ng/mL V_2O_5: 0, 0.15, 0.3, 0.61, 1.25, 2.5, 5, 10, 20 µg/cm^2 $NiSO_4$, $Fe_2(SO_4)_3$, TiO_2, SiO_2: 0, 1.23, 2.5, 5, 10, 20 µg/cm^2 $VOSO_4$: 0, 0.145, 0.29, 0.58, 1.16, 2.32 µg/cm^2 **Time to Analysis:** LPS: 0, 6, or 18 h ROFA: 0, 2,4,6 h V_2O_5: 0, 0.25, 0.5, 1, 2, 4, 6, 8h $NiSO_4$, $Fe_2(SO_4)_3$, TiO_2, SiO_2, $VOSO_4$: 6 h	**ROFA in BTE:** ROFA and ROFA leachate inhibition of LPS-induced TAP gene expression increases with exposure time and dose. Washed particles of ROFA at doses 2.5 to 10 mg/cm^2 significantly increased inducible TAP expression. **Soluble Metals in BTE:** V_2O_5 inhibition of LPS and IL-1β induced TAP gene expression increases with exposure time and dose. $NiSO_4$ exhibits non-significant dose dependent suppression of inducible TAP gene expression. $Fe_2(SO_4)_3$, TiO_2 and SiO_2 were found to have no effect. **A549:** Results with ROFA and V_2O_5 in BTE were replicated using the A549 cell line and IL-1β to induce hBD2 gene expression. **Cellular Viability:** Was not significantly affected in ROFA doses below 20 µg/cm^2 and V_2O_5/$VOSO_4$ doses below 2.5 µg/cm^2.
Reference: Koike and Kobayashi (2005, 088303) **Species:** Rat **Gender:** Male **Strains:** Wistar Kyoto **Age:** 8-10 wk **Weight:** 280-350 g **Cell Types:** AM, PBM (peripheral blood monocytes), T-cells (antigen sensitized)	Whole DEP: Diesel Exhaust Particles collected in the dilution tunnel of a diesel inhalation facility. (Ratio of organic extract to residual particles in the whole DEP was 3: 1.) Organic extract of DEP Residual particles of DEP OVA: Ovalbumin **Particle Size:** NR	**Route:** Cell Culture (1×10^6 cells/ml) **Dose/Concentration:** Whole DEP: 10, 30, 100 µg/mL Organic extract of DEP: 7.5, 22.5, 75 µg/mL Residual particles: 2.5, 7.5, 25 µg/mL **Time to Analysis:** 24 h post exposure	**Ia Antigen and Costimulatory Molecules:** Most control AM did not express these molecules. Whole DEP did not cause any increase in expression level. 20% of control PBM expressed Ia and 10% B7; expression of these molecules was significantly increased by whole DEP. Organic extract significantly increased the expression of Ia and B7 molecules on PBM similar to whole DEP. Residuals caused no effect. Organic extract-induced expression of Ia antigen in PBM was reduced by treatment with NAC. **AP Activity:** After exposure to organic extract, T cell proliferation was significantly increased by the addition of control PBM in a cell number-dependent manner. AP activity of PBM was increased over control by exposure to 3 µg/mL organic extract, although higher concentrations suppressed the activity of PBM. **Cytokine Production:** Organic extract treatment of PBM decrease IFN-γ production from T-cells stimulated by PBM. No significant effect on IL-4 observed. **HO-1 Protein Level:** Levels in PBM were significantly increased by exposure to whole DEP or organic extract. Levels induced by organic extract was diminished by NAC treatment.

Aerosol on day 28 after first ip; 60 min 3x/wk	**2 Wk PM Exposure/4 Wk OVA Aerosol Treatment:** The OVA alone group had significantly more airway collagen than the PM alone group. Histology showed significantly more collagen in the treatment than the air alone group. There was a significantly greater amount of goblet cells than the OVA alone group. **4 Wk OVA Aerosol/ 2 Wk PM Treatment:** The OVA treatment had significantly more goblet cells than the PM alone group. **6 Wk Concurrent PM and OVA Treatment:** Significantly more cells were observed in the OVA alone group over the treatment. The treatment had significantly more lymphocytes and significantly less macrophages than groups exposed to PM before or after OVA. Histology showed significantly more collagen in the treatment than the air or PM alone groups. The treatment had significantly more goblet cells than the OVA alone group.
Reference: Li et al. (2007, 093156) **Species:** Mouse **Gender:** Female **Strain:** BALB/c, C57BL/6 **Age:** 9 wk **Weight:** NR	DEP (2369-cc diesel engine manufactured by Isuzu Motor, operated at 1050 rpm, 80% load, commercial light oil) **Particle Size:** NR	**Route:** Inhalation **Dose/Concentration:** DEP: 103.1 ± 9.2 µg/m^3, CO: 3.5 ± 0.1 ppm, NO_2: 2.2 ± 0.3 ppm, SO_2: <0.01 ppm **Time to Analysis:** Protocol 1: Exposed 7h/day, 5days/wk. Sacrificed at day 0, week 1, 4, 8. Protocol 2: DE alone or DE+NAC 7h/d, 1-5 days.	**Airway Hyperresponsiveness:** Penh values increased in BALB/c mice compared to the control at day 0, but no significant changes occurred after this time. Penh values increased in C57BL/6 mice at 1wk compared to the control but returned to control levels at 8 wk. **BALF:** Compared to the other strain, the total number of cells and macrophages increased significantly at 1wk in C57BL/6 mice and at 8wk in BALB/c mice. Neutrophils, lymphocytes, MCP-1, IL-12, IL-10, IL-4, IL-13 increased significantly for both strains. No eosinophils were found. IL-1B and IFN-γ increased significantly in BALB/c mice compared to C57BL/6 mice. **HO-1 mRNA and Protein:** HO-1 mRNA was more marked in BALB/c mice at 1wk and C57BL/6 mice at 4 and 8 wk. HO-1 protein percentage changes from the control were greater in BALB/c mice at 1wk and C57BL/c mice at 8 wk. **NAC:** NAC inhibited the increased Penh values, total number of cells and macrophages in C57BL/6 mice at 1 wk and neutrophils and lymphocytes in both strains.
Reference: Li et al. (2009, 190457) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 6-8 wk **Weight:** NR	CAPs (downtown Los Angeles, CA from major freeway, traffic mainly passenger cars and diesel trucks; Jan. 2007 or Sept. 2006) Ultrafine carbon black (UFCB; used as control) **Particle Size:** Fine- <2.5 µm (diameter), UF- <0.15 µm (diameter)	**Route:** Intranasal Instillation **Dose/Concentration:** 0.5 µg PM in 50 µL suspension **Time to Analysis:** Day 1 exposed to PM or saline. Day 2 exposed to PM+OVA or OVA or saline alone. Repeated on days 4, 7, 9. Different experiment: NAC ip injected 4 h pre-instillation on days 1, 2, 4, 7, 9. All animals rested and OVA aerosol challenged 30 min on days 21, 22. Sacrificed day 23.	UFP alone had no effect on the lung. UFP+OVA significantly increased eosinophils, and OVA-specific IgG1 and IgE. The induction of eosinophils and IgG1 were inhibited by NAC. Generally, UFP+OVA mice had greater signs of inflammation than the other groups as determined by pulmonary histopathology and airway morphometry. UFP had a greater PAH content than fine particles. UFP significantly increased IL-5, IL-13, TNF-α, IL-6, KC, MCP-1, and MIP-1α.

AM pre-exposed to carbon or washed DEP. Loaded with particles. Incubated with S. pneumoniae, ATCC strain or clinical isolates.	**Effect of Time on Survival of S. Pneumoniae when Incubated with Carbon Loaded AM:** Loading AM with carbon significantly increased the bacterial survival. Bacteria opsonization decreased bacterial survival. **Effect of Carbon Load in AM on Survival of S. Pneumoniae:** Bacterial survival increased in a dose-dependent manner as the carbon particle load of AM increased. **Survival of S. Pneumoniae after Incubation with Carbon or Washed Diesel Loaded AM:** Bacterial survival increased in carbon loaded AM compared to the control. No difference existed with the washed diesel particles. **Survival of the ATCC Strain and Clinical Isolates of S. Pneumoniae when Incubated with Carbon Loaded AM or Control AM:** Carbon significantly increased the CFU of opsonized and unopsonized bacteria for the ATCC strain and clinical isolates. **Ability of carbon or washed diesel loaded AM, incubated with the ATCC strain of S. pneumoniae, to induce LPO of lung surfactant:** A 97% increase in the surfactant LPO occurred after incubation with washed diesel loaded AM compared to control AM. The effect of washed diesel particles was significantly greater than that of carbon particles. **LPO by carbon loaded AM incubated with the ATCC strain or clinical isolates in the presence of absence of surfactant:** LPO induced by AM increased when incubated with carbon loaded AM compared to control AM.

Study	Pollutant	Exposure	Effects
Reference: Matsumoto et al. (2006, 098017) **Species:** Mouse **Gender:** Female **Strains:** BALB/c **Age:** 6 wk **Weight:** 15-20 g	DE (collected from a 2369 cm^3 diesel engine operated at 1050 rpm and 80% load with commercial light oil; engine exhaust passed through a particulate air filter and charcoal filer) Diluted DE introduced into the exposure chamber. Composition of the DE: 3.5 ± 0.1 ppm CO, 2.2 ± 0.3 ppm NO_2, <0.01 ppm SO_2 and 103.1 ± 9.2 µg/m^3 DEP. **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** 100 µg/m^3 DE **Time to Analysis:** Mice were initially sensitized w/ OVA (20ug absorbed to 2 mg alum diluted with 0.5 mL saline) via ip injection on day 0, 6 and 7. Two wks later the mice were challenged with OVA (0.1mg in 0.1mL saline) intranasally on day 21. DE for 1d or 1,2, 3, 4 or 8 wk (at 7 h/day for 5 days/wk).	**Airway Hyperresponsiveness:** Exposure to DE significantly increased airway reactivity to methacholine after 1 wk in both 24 and 48 mg/mL Mch and after 4 wk in the 48 mg/mL. DE exposure caused an increase in airway sensitivity after 1 wk of exposure, 4 wk and 8 wk of exposure did not result in a significant increase. **BAL Cells:** The total cell count was increased after 1 wk of DE exposure. This increase was mostly due to an increase in eosinophils. After 1 wk the total cell count dropped drastically even after continuous exposure to DE. DE did not effect the number of CD3, CD4, CD8 or NK1 cells at any point in time. **Cytokine/Chemokine mRNA Levels:** DE exposure on day 1 caused an increase in mRNA levels of IL-4, IL-5 and IL-13 when compared to the control mice but longer periods of DE exposure failed to cause an increase. Protein levels of IL-4 were significantly elevated at compared to control at day 1, but did not persist with time. mRNA levels of MDC were increased at 1 wk of exposure (compared to control) but also decreased at time periods after. mRNA levels of RANTES were increased at 2 and 3 wk after exposure and remained elevated at 4 wk but not significantly. The level of RANTES protein increased as the weeks went along, but increased significantly only at 8 wk. **Histopathology:** OVA sensitization caused an increase peribronchial and perivascular infiltration of inflammatory cells which peaked at 1 wk after exposure and decreased afterward. DE exposure did not cause/show any additional signs of inflammation.
Reference: Morishita et al. (2004, 087979) **Species:** Rat **Gender:** Male **Strain:** Brown-Norway **Age:** 10-12 wk	CAPs (generated from ambient air in an urban Detroit community). **Particle Size:** 0.1-2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** July 676 µg/$m^{3;}$ September 313 µg/m^3 **Time to Analysis:** First rats were sensitized (days 1-3) and challenged (days 14-16) with saline (control) or OVA by intranasal instillation (5% in saline, 150 µL/nasal passage). 4 days after the last intranasal challenge, rats began exposure in the chambers. Exposures were 10 h long. The July exposure was for 4 consecutive days. The September exposure was for 5 consecutive days.	**Recovery of Trace Elements in Animal Lung Tissues:** July Exposure- Anthropogenic trace elements were below limit of detection in pulmonary tissue of animals exposed to July CAPs. September Exposure- Several elements were recovered from pulmonary tissue during the Sept. exposure. La concentrations were increased in both control/CAPs exposure and in the OVA/CAPs exposure groups. V concentration was increased in OVA/CAPs exposed animals but not in rats exposed to just CAPs. S content was only significant in animals exposed to OVA/CAPs compared to the non-exposed control. **Particle Characterization:** July PM had an average mass concentration twice as high as the September mass concentration. S concentration was four-folds higher in July PM. In the September PM- the concentration of La was 12.5 fold higher than in July PM, V was 2.7 fold higher than in July PM and Mn was 1.5 fold higher than in July PM. **BALF Analysis:** Eosinophil concentration was not significantly different when comparing rats exposed to CAPs only in either July or September (this was explained by the elapsed time between exposure and BALF collection). However OVA and CAP exposure in the September group led to elevated eosinophil levels. Similarly, the protein content was only significantly increased in the September OVA/CAP exposed rats, compared to the control group.

Reference: Nygaard et al. (2005, 088655) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 6-7 wk	Coarse and fine ambient air particles collected in Rome (spring), Oslo (1-summer, fine only, 2- following spring, fine and coarse), Lodz (summer) and Amsterdam (spring). These represent areas with high population and dominance of traffic. DEP (Standard reference material 1650a) **Particle Size:** Fine PM 0.1-2.5 µm; Coarse PM 2.5-10 µm	**Route:** Subcutaneous Injection into mouse footpads. **Dose/Concentration:** 100 µg of particle **Time to Analysis:** Animals were in eight groups: 1. Control- Hank's Balanced Salt Solution 2. OVA- 50 ug 3. OVA (50 µg)+ Amsterdam Coarse PM (100 µg) 4. OVA (50 µg)+ Amsterdam Fine PM (100 µg) 5. OVA (50 µg)+ Lodz Coarse PM (100 µg) 6. OVA (50 µg)+ Lodz Fine PM (100 µg) 7. 5. OVA (50 µg)+ Oslo Coarse PM (100 µg) 8. OVA (50 µg)+ Oslo Fine PM (100 µg) Analysis 5 days after injection.	**Cell Numbers and Cell Phenotypes in the Lymph Node**: The overall number of B lymphocytes, lymph node cells, PLN cells, and the expression of MHC class II, CD86 and CD23 on B lymphocytes were increased by coexposure of OVA+ the particles compared to the OVA or particle groups alone. The OVA + particle groups displayed a significant decrease in T lymphocytes. Particles only significantly increased the number of lymph node cells and MHC Class II expression. There were no differences observed between coarse and fine PM fractions. **Cytokine Production by Lymph Node (ex vivo culture of popliteal lymph node cells):** The OVA + particle (DEP and Oslo1 only) significantly increased IL-4 and IL-10 levels. No change was observed in IFN-γ. The particle groups only increased IL-4 and IL-10. All coarse and fine particle fractions co-exposed with OVA significantly increased IL-4 and IL-10 compared to OVA alone. There was no significant difference between coarse and fine particles. IFN-γ levels were not significantly affected by most of the groups, but the fine fractions of PM consistently produced higher levels of IFN-γ. **Lymph Node Histology:** OVA + particle groups resulted in significantly enlarged lymph nodes and the formation of germinal centers.
Reference: Nygaard et al. (2005, 087980) **Species:** Mouse **Gender:** Female **Strains:** BALB/c **Age:** 6-8 wk	Polysterene Particles (PSP) **Particle Size:** 0.1 µm (diameter)	**Route:** Subcutaneous Injection into footpads. **Dose/Concentration:** 40 µg PSP (5.94×10^{10} particles) per injection suspended in HBSS. One injection per footpad **Time to Analysis:** 1. HBSS 2. OVA (10 µg per injection) 3. PSP (40 µg per injection) 4. OVA (10 µg per injection) + PSP (40 µg per injection). Antibody experiments: reinjected with 10 µg OVA on day 21. Killed on day 26. Popliteal lymph node cell experiments-- animals injected. Killed 1 to 21 days post-injection.	**OVA-specific IgE, IgG1 and IgG2a Antibodies:** Analysis at day 26 indicated IgE, IgG1 levels were significantly higher in mice exposed to OVA+PSP compared to mice injected with HBSS, OVA or PSP. No significant difference was observed for IgG2a levels. **Number of Particle Containing Cells:** There was no significant difference between PSP alone and OVA+PSP. Throughout days 0 -21 the number of particle-containing cells in the PSP or OVA+ PSP groups were significantly greater than the HBSS group. **Total Cell Numbers, B and T Lymphocytes and MHC class II Expression:** The total cell number and B lymphocytes significantly increased by coexposure to OVA+ PSP when compared to the other groups. Both OVA and OVA+PSP increased T lymphocytes on Days 1, 3 and 5. MCH class II expression was significantly higher in the OVA+PSP group on days 5, 7 and 21 than other groups. **Cell Types and Surface Markers:** The number of CD40+ B Lymphocytes showed a slight but significant decrease with OVA+PSP and OVA compared to HBSS and PSP. CD86+, CD23+ and CD69+ B lymphocytes were significantly higher in OVA+PSP group than other groups. PSP alone did not affect CD86+ or CD23+ levels. **Cytokine Production:** IL-4 and IL-10 were significantly higher in the OVA+PSP group when compared to the other groups. OVA alone caused a slight increase compared to PSP. PSP did not alter IL-4 or IL-10 levels.

Reference: Nygaard et al. (2004, 058558) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 6-7 wk **Weight:** NR	CB (carbon black/DEP) Polystrene Particles (PSP) **Particle Size:** PSP diameter: 0.0588, 0.202, 1.053, 4.64 or 11.14 µm	**Route:** Single subcutaneous injection into footpad **Dose/Concentration:** 10 µg OVA + 40 µg (low dose) or 200 µg (high dose) of particles **Time to Analysis:** 5 days after OVA injection	**OVA Specific IgE and Ig2a:** OVA with CB, DEP or PSP of diameters 0.0588 and 0.202 µm increased IgE compared to OVA alone, as well as the 1.053, 4.64 and 11.14 µm PSP. OVA with 0.0588 µm PSP or CB significantly increased IgG2a compared to OVA alone. **Primary Cellular Response:** All OVA and PSP groups (except the low dose of 11.14 µm PSP) had more total lymph node cell numbers than the OVA alone group. The low and high does groups of 0.202 µm PSP had the greatest amount of cell proliferation and lymphoblasts. The OVA and 0.202 PSP treatment produced the greatest amounts of B lymphocytes, IL-4, IL-10 and IFN-γ. IL-2 in the PLN cells was significantly lower in both dosage groups of OVA and 0.202 PSP than the OVA control. **Particle Mass, Size, Number and Surface Area:** Total particle surface area explained 64% of the variance in the IgE levels. 60-80% variance of the PLN cellular parameters (except CD23) were explained by total particle surface area, number and diameter.
Reference: Reed et al. (2008, 156903) **Species:** Mouse **Gender:** Male, Female (only BALB/c) **Strain:** C57BL/6, A/J, BALB/c **Age:** NR **Weight:** NR	GEE (two 1996 General Motors 4.3-L V-6 engines; regular, unleaded, non-oxygenated, non-reformulated gasoline blended to US average consumption for summer 2001 and winter 2001-2002-Chevron-Phillips) **Particle Size:** 150 nm (MMAD)	**Route:** Whole-body Inhalation **Dose/Concentration:** PM; Low- 6.6 ± 3.7 µg/m^3, Medium- 30.3 ± 11.8 µg/m^3, High- 59.1 ± 28.3 µg/m^3 **Time to Analysis:** A/J- 6 h/day, 7days/wk, 3 days-6 mo. C57BL/6- 1wk exposure. Instillation of P. aeruginosa. Killed 18 h postinstillation. BALB/c- Pregnant females exposed GD 1 and throughout gestation. Offspring exposures continued until 4wk-old. Half of offspring sensitized to OVA. Tested for airway reactivity by methacholine challenge 48 h post-instillation and euthanized.	The kidney weight of female A/J mice decreased at 6 mo. and was strongly related to PM by the removal of emission PM. PM-containing macrophages increased by 6 mo. Hypomethylation occurred in females at 1 wk. The clearance of P. aeruginosa was unaffected by exposure. Serum total IgE significantly and dose-dependently increased. OVA-specific IgE and IgG1 gave slight exposure-related evidence but were not significant.
Reference: Roberts et al. (2007, 097623) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** 10 wk **Weight:** 250-300 g	R-Total = ROFA (Residual oily fish ash) R-Soluble = Soluble fraction of ROFA R-Chelex = R-Soluble+Chelex (insoluble resin) **Particle Size:** 2.2 µm (mean diameter)	**Route:** IT Instillation **Dose/Concentration:** 10 mg/kg (2.5-3 mg) **Time to Analysis:** Pre-exposure to ROFA samples on Day 0. Inoculation with 5×10^4 L. Monocytogenes or saline on day 3. Sacrifice on days 6, 8, 10.	**Uninfected Groups:** Compared to the controls, the R-total and R-soluble groups had increased LDH, PMNs, lymphocytes and AMs. The R-total group had a slight, but significant increase in IL-6 and the R-soluble group had a decrease in IL-2. **Infected Groups:** The R-soluble group had increased levels of LDH (which also increased for the R-total group), albumin, BALF cells, NK cells, PMA-stimulated and zyomason-stimulated CL compared to all other groups at various time points. NOX was significantly elevated in the R-soluble group at early time points, but in later time points R-soluble and R-total AMs produced less NOX than the controls. IL-10 and IL-6 increased in the R-soluble group, while IL-12, IL-4 and IL-2 decreased. IL-12 also decreased in the R-total group.
Reference: Saxena et al. (2003, 054395) **Species:** Mouse **Gender:** Female **Strain:** C57B1/6J **Age:** 18-30 wk **Weight:** NR	DEPs (standard) **Particle Size:** NR	**Route:** Intrapulmonary Instillation **Dose/Concentration:** 100 µg/mouse **Time to Analysis:** Pre-exposure to 2.5×10^4 bacillus Calmette-Guerin bacteria (BC G) with or without coadministration of DEP. Sacrifice 5 wk later.	The BC G + DEP group had four times the BC G lung load than BC G alone. The load was significantly greater in other organs in the BC G + DEP group. Interstitial lymphocytes, T, B and NK cells were increased in the BC G + DEP group over the DEP-alone group. DEP caused no release of NO by AMs, but inhibited the release of NO in response to IFN-γ. Except for CD8 cells, no increase in IFN-γ was seen in the BC G + DEP group.

Study	Pollutant	Exposure	Effects
Reference: Schneider et al. (2005, 088368) **Species:** Mouse **Strain:** BALB/c **Cell Line:** RAW 264.7	SRM 1648 (greater than 63% inOC; 4-7% OC; Si, S, Fe, Al, K greater than 1% by weight; Mg, Pb, Na, Zn, Cl, Ti, Cu, As, Cr, Ba, Br, Mn less than 1%) TiO_2 **Particle Size:** TiO_2 = 0.3 µm average, 1.0 µm max SRM 1648 = 0.4 µm (mean diameter)	**Route:** Cell Culture (625,000 cells/cm^2 in 96 well plate) **Dose/Concentration:** 0, 7.8, 15.6, 31.2, and 62.5 µg/cm^2 **Time to Analysis:** 1, 3, 6, and 12 h	No significant toxicity was exhibited by SRM 1648. The rate of dye oxidation was significantly higher in SRM 1648-exposed cells. SRM 1648 significantly increased reduced glutathione compared to the control at the 12-h time point. SRM 1648 increased GSH and concurrently caused significant PGE2 production compared to the no ester control at the 6-h and 12-h time points.
Reference: Schober et al. (2006, 097321) **Species:** Human **Gender:** Male and Female **Age:** 21-39 yr treatment group; 23-32 yr control group **Tissue Type:** Whole blood samples	PM - organic extracts of airborne sample AERex1d - urban aerosol 1 day sample (total air volume - 1270m^3) AERex5d - urban aerosol 5 day sample (total air volume - 6230m^3) rBet v 1 (birch pollen allergen 1a, Biomay, Vienna, Austria) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 100 µL heparinized whole blood **Time to Analysis:** Blood stimulated with PBS/IL-3 for 10 min. Incubated with rBet v 1 alone or with AERex for 20 min. Ice bath 5 min. Incubated with antibody reagent 20 min.	Nine organic compound classes were identified in AERex1d and AERex5d, with AERex1d having 20 times more PAHs. Basophil activation increased in all treatment groups up to 90%, with AERex1d being the most pronounced. 5-50 fold lower concentrations of AERex1d were needed to achieve the maximal effect on basophil activation. AERex-induced enhancement of CD63 upregulation of rBet v 1 in sensitized basophils occurred in a dose-dependent manner. The AERex-alone treatment did not affect CD63 expression.
Reference: Shwe et al. (2005, 111553) **Species:** Mouse **Gender:** Male **Strains:** BALB/c **Age:** 8 wk **Weight:** NR	CB = carbon black particles (Degussa, Germany) CB14: C: 96.79% H: 0.19% N: 0.13% S: 0.11% Ash: 0.05% Others including O: 2.74% CB95: C: 97.98% H: 0.15% N: 0.28% S: 0.46% Others including O: 1.14% **Particle Size:** CB14 = 14 nm (primary particle size); CB95 = 95 nm (primary particle size)	**Route:** IT instillation **Dose/Concentration:** 25, 125, or 625 µg in 1 mL saline solution **Time to Analysis:** 1/wk for 4 wk; 4 or 24 h after last instillation	**BALF Cells**: In CB14, the total number of BAL cells increased significantly and dose-dependently. In CB95, only the 625µg dose showed a significant increase. **Cytokine and Chemokine:** For CB14 and CB95, 125 or 625 µg showed a significant IL-1B increase in a dose-dependent manner. For CB14, only the 625 µg dose showed a significant IL-6 increase. No difference was observed in the CB95 group. For CB14, only larger doses showed a significant TNF-α increase. For CB95, no significant differences were observed. **In BAL Fluid:** CCL-2 production was significantly increased for the 625µg dose in both the CB14 and CB95 groups. CCL-3 production was significantly increased for the larger doses in both the CB14 and CB95 groups. **Splenic Lymphocytes:** No significant differences were detected among the CB14 dosages, except for CD8+. No significant differences were observed among the various groups for CB95. **Deposition in Lymph Nodes:** For all dosages, greater deposition of CB14 than CB95 was observed. **Chemokine mRNA Expression in Lungs and Lymph Nodes:** At 125 µg, significant increases of CLL-3 mRNA expression was observed for CB14; for CB95, no differences were detected.

Study	Pollutant	Exposure	Effects
Reference: Sigaud et al. (2007, 096100) **Species:** Mouse **Gender:** Male **Strains:** BALB/c **Age:** 8-10 wk **Weight:** NR	CAPs: Concentrated Ambient Particles (Collected from ambient Boston air on Teflon filters.) TiO_2 IFN-γ S. pneumoniae (ATCC 6303, American Type Culture Collection, Manassas, VA) **Particle Size:** CAPs: <2.5 µm	**Route:** IFN-γ priming: aerosol Particle exposure and infection: Intranasal Instillation **Dose/Concentration:** CAPS or TiO_2: 50 µg/50 µL PBS S. pneumoniae: 105CFU/25 µl saline **Time to Analysis:** Primed for 15 min One time particle exposure 3 h post priming with lung RNA analyzed 3, 6, 24 h after exposure Sacrificed 24 h after exposure or one time infection	**Inflammation:** Saline-primed and unprimed mice exposed to CAPs produced a significant increase in PMNs in the lung (100% more than mice exposed to TiO_2.) Groups primed with IFN-γ then exposed to CAPs produced a strong inflammatory response, a 2.5 increase in PMNs when compared to the increase caused by PBS+ CAPs exposure. **Cytokine Levels:** IFN-γ primed and CAPs exposed groups **Inflammation+ S. Pneumo Infection:** Saline-primed and unprimed mice exposed to CAPs produced a significant increase in PMNs in the lung (100% more than mice exposed to TiO_2.) Groups primed with IFN-y then exposed to CAPs produced a strong inflammatory response, a 2.5 increase in PMNs when compared to the increase caused by PBS+CAPs exposure. **Cytokine Levels:** IFN-y primed and CAPs exposed groups showed a 1.5-fold increase over the control. **PMNs:** Treatment with CAPs enhanced inflammation, causing a 2-fold increase in PMN numbers as compared to the infected control. IFN-y+CAPs+S. pneumo produced a 3.5 fold increase compared to the infected control and a 1.6-fold increase compared to PBS+CAPs+S.pneumo. Despite increased numbers of PMNs in the IFN-y+CAPs groups, the lungs were unable to clear the S. pneumo infection. **Bacterial Load:** Control groups showed efficient clearance of bacteria after infection. Unprimed, CAPs-treated, infected groups did not show a decrease in bacterial numbers. IFN-y+CAPs showed a 2.5-fold increase in bacterial numbers. **Histopathology:** Indicated moderate pneumonia in PBS+CAPs and severe pneumonia in IFN-y+CAPs. The other groups did not indicate areas of pneumonia. **Bacterial Uptake AM and PMN Cells:** In all the treated groups, the bacterial content in AMs showed a decrease, with a more marked decrease in the IFN-y+CAPs group, but these decreases were not statistically significant. Groups exposed to CAPs showed a statistically significant decrease in bacterial uptake by PMNs. **ROS Levels in AM and PMN Cells:** Intracellular ROS significantly increased in AM cells in the IFN-y+CAPs group, approximately 50% greater than controls. In PMNs, iROS increased 100% in the IFN-y+CAPs groups as compared to the controls.

Study	Pollutant	Exposure	Effects
Reference: Steerenberg et al. (2004, 087474) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** 6-8 wk	DEP:SRM1650a (NIST, Gaithersburg, MD EHC-93: ambient PM (Ottawa, Canada) O_3 (positive control) L. mono: Listeria monocytogenes (strain L242/73 type 4B) **Particle Size:** DEP, EHC-93: NR	**Route:** DEP/EHC-93: intranasal droplet; O_3: Whole-body inhalation **Dose/Concentration:** DEP/EHC-93: 50 µg (1.0 mg/ml) O_3: 2mg/m^3 L. mono: 0.2 or 0.3 ml (5x106 PFU/ml) *I have emailed author regarding correct dose **Time to Analysis:** DEP/EHC-93: 1/day for 7 days (-7 days to -1 days) O_3 24 h/day for 7 days (-7 days to -1 daysR All rats infected on day 0. Sacrificed on days 3, 4, or 5.	**Body weight:** Growth declined for O_3 exposed group while DEP or EHC-93 groups grew progressively. Exposure to L. mono caused all groups to decline in weight. **Bacterial Count in the Lung:** The number of bacteria in the lung of those rats exposed to O_3 was significantly greater than those exposed to saline. No differences in bacteria number were found for rats exposed to saline, EHC-93 or DEP at any time. **Bacterial Count in the Spleen:** The O_3 exposed group exhibited statistically significant increases in bacteria numbers when compared to the saline-treated group. No differences in bacteria number were found for rats exposed to saline, EHC-93 or DEP at any time. Exposure to O_3 decreases the defense of the respiratory tract against L. mono infection; however, DEP and EHC-93 did not appear to affect the host defense system in regards to clearing/fighting L. mono.
Reference: Steerenberg et al. (2005, 088649) **Species:** Mouse **Gender:** Male **Strain:** BALB/cByJ.ico **Age:** 6-8 wk	PM: collected from Rome, Oslo, Lodz, Amsterdam and De Zilk during the spring, summer and winter. Rome, Oslo, Lodz and Amsterdam represent areas with high population and dominance of traffic. De Zilk, selected as a negative control site, has low traffic emissions and natural allergens. EHC-93: used as a positive control OVA: Ovalbumin **Particle Size:** Coarse PM: 2.5 - 10.0 µm (MMAD); Fine PM: 0.1 - 2.5 µm (MMAD); Ultrafine: <0.1 µm (MMAD); EHC-93: NR	**Route:** Intranasal Exposure OVA challenge: aerosol **Dose/Concentration:** PM: 450 µg PM (at 0, 3, or 9 mg/ml) OVA sensitization: 50 µg (0.4 mg/ml) . OVA challenge: 20 µg (0.4 mg/ml) EHC-93 was administered at 0 - 900 µg to evaluate any dose-response relationship. **Time to Analysis:** Sensitization and PM exposure on days 0, 14 Challenged on days 35, 38, 41 for 20 min/day Sacrificed on day 42	**Effects of Coarse and Fine Particles:** Immunoglobulins: 6/13 of the coarse and 9/13 fine PM samples induced an increase in IgE and IgG1when compared to the control. IgG2a levels were increased in 3/13 of the coarse and 5/13 of the fine PM. Particles from De Zilk induced all three immunoglobulins, except the fine PM did not induce IgG2a. De Zilk was intended as a negative control (see Table 3). Analysis among the sites comparing the subclasses of antibodies indicated a rank as follows: Lodz >Rome ≥ Oslo. **Histopathology:** 9/13 of the coarse PM samples and 5/13 of the fine PM samples induced an inflammatory response. **BALF Cells:** Lodz (spring/ summer) coarse and fine PM induced a significant increase in eosinophils, neutrophils and monocytes. The coarse and fine PM from Rome (spring) induced an increase in neutrophils and the coarse PM induced an increase in eosinophils. Also both Lodz and Rome from the coarse PM from the spring induced an increase in macrophages. Other PM samples did not have an effect on BAL cell counts. **Cytokine Production:** None of the samples produced a significant effect on IL-4 levels. IFN-γ levels were significantly decreased in mice exposed to the fine PM fraction (in 8/13 of the samples) when compared to control. Coarse particle exposure did not appear to affect IFN-γ levels. TNF-α levels were significantly increased (in 2 of the 13 samples) when exposed to coarse PM; fine PM showed similar responses compared to the OVA only group. IL-5 was significantly increased in 4/13 of the coarse and fine PM samples. **Analysis of PM Components:** Samples from Lodz, Oslo and Rome (all spring) were evaluated and the water-soluble coarse PM fraction showed increased immunoglobulin and pathological responses and the water-insoluble fine PM fraction from Lodz (Spring) showed increased reactivity. Leukocytes and cytokines showed no major differences.

Reference: Steerenberg et al. (2004, 087981) **Species:** Mouse **Gender:** Male **Strain:** BALB/cByJ.ico **Age:** 6-8 wk **Treatment:** 1. C.D2-Vil6: Nramp1S and Nramp1R deficient 2. B6.129P2: Nos2tmLau: iNOS deficient 3. BALB/clL4 (tm2Nnt): deficient in IL-4 4. BALB/c (wild type) pretreated with N-Acetylcysteine (NAC)	EHC-93 OVA **Particle Size:** NR	**Route:** Sensitization, Challenge: Intranasal NAC: IP injection **Dose/Concentration:** OVA: 200 µg (0.4 mg/ml) EHC-93: 150 µg (3 mg/ml) NAC: 320 mg/kg **Time to Analysis:** OVA-only or OVA+EHC-93 sensitization on days 0 and 14. Some mice received NAC before intranasal exposure on days 0 and 14 OVA challenge on days 35, 38 and 41 Sacrificed on day 42	**Natural-Resistance-Associated Macrophage Protein 1 (Nramp1):** When exposed to only OVA, Nramp1S evoked less of an antibody responses (IgE, IgG1 and IgG2a) compared to Nramp1RHowever when coexposed to OVA and EHC-93, the level of increased production of antibodies was similar in both groups. After coexposure, the wild-type showed increased histopathological lesions, whereas the macrophage-stimulation-deficient types showed only a slight increase (not significant). IL-4, IFN-γ, TNF-α and IL-5 levels were similar in wild-type and the Nramp1 strains. **Pretreatment with NAC:** IgG2a concentration was increased further in the group pretreated with NAC. The wild-type mice and the NAC pretreated mice showed similar histopathological lesion patterns. IL-4 levels were similar in wild-type and the NAC pretreated mice. (IFN-γ, TNF-α and IL-5 levels not reported) **Inducible Nitric Oxide Synthase (iNOS):** The wild-type and the iNOS-deficient mice had similar levels of increased IgE antibody production. The IgG1 and IgG2a antibody response was twice as great in the iNOS-deficient mice compared to the wild type. The wild-type and the iNOS-deficient mice showed similar histopathological lesions. No differences in BAL cells or cytokines were observed between the wild-type and iNOS-deficient mice. **IL-4:** The IL-4-deficient mice did not produce an increase in IgE or IgG1 antibodies, as was seen in the wild-type mice. The IgG2a antibody response in the IL-4-deficient mice was similar to the wild type response resulting in adjuvant activity for the IgG2a antibodies. Overall the histological response of the wild-type mice was greater compared to the IL-4 deficient mice. There was no real difference between the two strains observed in the BAL cells, except IL-5 was significantly lower in the IL-4-deficient mice.

Study	Pollutant	Exposure	Effects
Reference: Stevens et al. (2008, 155363) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 10-12 wk **Weight:** 17-20 g	DE: generated using a 30 kW 4-cylinder Deutz BF4M1008 diesel engine connected to a 22.3 kW Saylor Bell air compressor. The engine was operated on diesel fuel purchased from a service station in Research Triangle Park, NC. The engine was operated at a steady-state, approx. 20% of engine's full load. High composition: O_2: 4.3 ± 0.07 ppm NO: 9.2 ± 0.30 ppm NO_2: 1.1 ± 0.05 ppm SO_2: 0.2 ± 0.10 ppm Low composition: O_2, NO, NO_2, SO_2 below detection limits **Particle Size:** NR	**Route:** Whole-body Inhalation OVA immunization and challenge: intranasal **Dose/Concentration:** High = 2000 µg/m^3 Low = 500 µg/m^3 **Time to Analysis:** DE exposure for 4 h/day on days 0-4. OVA immunization 40 min after DE exposure on days 0-2 Challenged on days 18 and 28. Sacrificed 4 h after last exposure of day 4 for gene set analysis or 18, 48, or 96 h after the last challenge	**IgE Antibody Production:** In the absence OVA, IgE antibodies were not detected. 18, 48 and 96 h following OVA, mice exposed to low and high doses of DE had an increase in antibodies over time. Mice exposed to high dose had an increase (non-significant) to the OVA exposed control at the 48 h time mark **BAL Cells:** Cell counts at 18 and 96 h after OVA treatment did not differ among treatment groups. At 48 h the number of eosinophils, neutrophils and lymphocytes were significantly increased in mice exposed to both high and low concentrations of DE. With DE exposure alone, only neutrophils were statistically increased in the high DE concentration. This indicates the combination exposure of DE and an antigen is essential to promote the development of allergic lung disease. **BAL Cytokines:** IL-6 production showed a dose-dependent and time-dependent increase, but was significantly increase in the high dose group at 96 h. The high dose group saw a non significant increase in IL-10 levels over time. The greatest increase in IL-10 for the low dose group occurred18 h after OVA stimulation. **Pulmonary Inflammation and Lung Injury:** No differences among the groups were observed for macrophage, lymphocyte, neutrophil and eosinophil counts. Protein and LDH levels were not found to be increased in the BALF of any group. **Gene Analysis:** Pair wise comparisons revealed significant gene set difference between the high DE and control groups. Comparison of the high DE/OVA versus air/OVA showed significant changes in 23 gene sets, including genes involved in oxidative stress responses. The high DE/saline versus the air/saline showed significantly altered pathways. Altered pathways include those for cell adhesion, cell cycle control, apoptosis, growth and differentiation, and cytokine signaling. The results show that relatively short exposures to DE cause mild increases in immunologic sensitization to allergen.

Study	Pollutant	Exposure	Effects
Reference: Takizawa et al. (2003, 157039) **Species:** Human **Cell Lines:** Normal Small Airway Epithelial Cells and Bronchial Epithelial Cells (BET-1A)	Suspended DEP: collected using a 2,300-cc Isuzu diesel engine using standard diesel fuel at 1,050 rpm under a load of 6 torque. DE exposure in vitro (air exposure): collected using a 2,300-ml Isuzu diesel engine at 1,050 rpm. Composition: Fine particles: 1 mg/m^3 CO: 10.6 ppm NO_2: 7.3 ppm SO_2: 3.3 ppm **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Suspended DEP: varying doses from 0-50 µg/ml IL-13: varying doses from 0-25 ng/ml DE exposure in vitro (air exposure): 100 µg/m^3 **Time to Analysis:** Cells were exposed to varying concentrations of suspended DEP for up to 24 h. NF-κB: analyzed at 6 h after suspended DEP exposure Air exposure at 0, 2, 4, 8 or 14 h	Preliminary experiments indicated that DEP at 0.1- 50 µg/mL had no significant cytotoxicity to BET-1A cells and human bronchial epithelial cells (as analyzed by LDH levels). **Eotaxin Production:** (Eotaxin is a cc chemokine that plays a role in eosinophil accumulation in a variety of allergic disorders) Epithelial and BET-1A cells treated with suspended DEP or IL- showed a dose-dependent stimulatory effect on eotaxin release or production. Simultaneous exposure to 25 ng/mL IL-13 and DEP depicted an additive effect for both cell types. **Eotaxin mRNA:** At 25 µg/mL, suspended DEP showed a time-dependent effect on eotaxin mRNA levels up to 12 h in both cell types. Extracted RNA from human bronchial epithelial cells exposed to varying doses of DEP showed a dose-dependent effect for both cell types (up to 25 µg/mL DEP) on eotaxin mRNA levels after 12 h of exposure. IL-13 also induced a dose-dependent increase on eotaxin mRNA levels in cells in both cell types. Combination of IL-13 and DEP showed an additive effect on mRNA levels in BET-1A cells. DE exposure in vitro also showed a time-dependent stimulatory effect on eotaxin production in BET-1A cells. **NF-κB / STAT6 Activation:** (it has been suggested that NF-κB plays a role in the trans-criptional regulation of eotaxin gene expression) Cells exposed to 1-25 µg/mL DEP for 6 h increased NF-κB. BET-1A cells treated with suspended DEP failed to activate STAT6. **Effect of NAC and PDTC on Eotaxin mRNA Levels:** (NAC and PDTC are antioxidant reagents with inhibitory effects on NF-κB activation) in BET-1A, both NAC and PDTC showed a dose-dependent inhibitory effect on DEP-induced eotaxin production. Both reagents also blocked DEP-induced eotaxin mRNA levels in BET-1A cells. NAC and PDTC did not suppress eotaxin production or eotaxin mRNA levels in IL-13 stimulated BET-1A cells. In addition pre-treatment with NAC attenuated NF-κB activation induced by DEP but had no effect on STAT6 induction by IL-13. These findings suggest that DEP stimulated eotaxin gene expression via NF-κB dependent, but STAT6-independent, pathways.

Study	Pollutant	Exposure	Effects
Reference: Tesfaigzi et al. (2005, 156116) **Species:** Rat **Gender:** Male **Strain:** Brown-Norway **Age:** 6 wk	PM: Wood smoke generated from a conventional wood stove that has a 0.5m^3 firebox and a sliding gate air intake damper. The stove was operated over a 3-phase burn cycle that spanned 6 h. Fire was started (initiated exposure) with unprinted / unbleached newspaper and a mix of black and white oak. Wood smoke components: organic material, small amounts of EC and metals and associated analytes. **Particle Size:** 0.36 µm (MMAD)	**Route:** Whole-body Inhalation **Dose/Concentration:** PM: 1000 µg/m^3 **Time to Analysis:** Exposed to wood smoke or filtered air 6 h/day for 70 consecutive days OVA IP injection immunization on days 2, 9 OVA aerosol exposure 2 h/day on days 67-70 following daily exposure to wood smoke or filtered air Sacrificed day 70	**Body Weight and Respiratory Function:** No difference in clinical signs or body weight was observed when comparing the two rat groups. The wood smoke exposed group had a 45% lower dynamic lung compliance when compared to those exposed to the filtered air group before the methacholine challenge. Challenging the rats with methacholine caused a decrease in dynamic lung compliance in both groups, but the decrease was greater in the air-exposed group. At the highest dose of methacholine, the dynamic lung compliance in controls was similar to the baseline value of the smoke-exposed group. No significant differences in total pulmonary resistance were observed. Wood smoke exposed rats had a 10% increase in functional residual capacity than the air-exposed group. **BAL Cells and Cytokines:** There was no difference in lymphocyte, eosinophil or neutrophils in the BALF of either group. There was an increase, though not statistically significant, in macrophages the wood smoke exposed group when compared to the filtered air group. In the BALF, IFN-γ and IL-1ß levels were significantly decreased, IL-4 and GRO-α levels were increased in rats exposed to wood smoke compared to filtered air. Serum IgE levels experienced a reduction trend in the wood smoke group, but it did not reach significance. Both groups showed mild signs of inflammation. The average eosinophils present in stained tissue was 21% higher in the wood smoke exposed group compared to the air exposed.
Reference: Tomita et al. (2006, 097827) **Species:** Mouse **Gender:** Female **Strain:** C57BL/6J; AHR-deficient; mEH-deficient; ARNT floxed (loxP sequences inserted in Arnt gene); Tcell-specific ARNT-deficient **Age:** 7 wk **Weight:** 20 g	DEP: two independent preparations fractionated into 13 different fractions based on acidic and basic functionality (one from light-duty, 4-cylinder diesel engine using standard diesel fueled and other generated from A4JB-type, Isuzu automobile, Japan) Individual PAH tested (Osaka, Japan): BbF = benzo[b]fluoranthene BeP = Benzo[e]pyrene IDP = Indeno[1,2,3-cd]pyrene BpPe = Benzo[ghi]perylene BaP = Benzo[a]pyrene BkF = Benzo[k]fluoranthene Per = Perylene DBA = Dibenzo[a,h]anthracene **Particle Size:** NR	**Route:** Intraperitoneal Injection **Dose/Concentration:** DEP, fractionated DEP or PAH compounds: 0.5 µg - 10 mg/kg bw in 50 µl of olive oil **Time to Analysis:** Single, sacrificed 3 days post-exposure.	**Effect on Thymus:** DEP treatment (10 mg/kg of body weight) caused severe atrophy of the thymus while the spleen and lymph nodes appeared normal. Three days following DEP treatment showed a marked reduction in thymus size. The total number of thymocytes was reduced by more than 70% mostly due to a massive reduction in DP cells (CD4+CD8+). DEP induced no significant alterations in the cell numbers of CD4/CD8 ratios in the spleen and lymph nodes. **DEP Extracts:** Only the WAC (carbonic acid fraction) and BE (weak basic fraction) did not produce a significant reduction in thymocyte numbers in vivo. Among the active fractions, 7 produced a marked selective loss of immature DP thymocytes, similar to the crude extract of DEP. **PAH Effects:** Thymic involution was severely induced by the N and various other fractions. 7 out of the 8 PAH compounds were significantly effective in decreasing the number of thymocytes upon in vivo exposure. Only BpPe did not have an effect. **AHR/ARNT and mEH Deficient Mice (BaP and DEP only):** In the absence of AHR, BaP treatment did not result in a loss of thymocytes. Like DEP, BaP produced severe thymic involution in mEH-deficient mice. DEP-mediated thymic involution was significantly enhanced in mEH-deficient mice.

Study	Pollutant	Exposure	Effects
Reference: Verstraelen et al. (2005, 096872) **Species:** Human **Tissue/Cell Types:** Monocyte-derived dendritic cells (Mo-DC) Cord blood samples of seven women were collected from umbilical vessels of placentas of normal, full-term infants.	DEP- SRM 2975 **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** DEP in varying concentrations: 0.2, 2, 20, 200, 2000 ng/mL LPS 100 ng/mL **Time to Analysis:** 24 h	**Biological Markers**: Exposure to DEP alone did not alter expression levels of HLA-DR, CD86 or CD83. Treatment with LPS alone caused a non-significant increase in all three markers when compared to the control. Treatment with DEP+LPS caused a significant increase in the expression of CD83 and a non-significant increased expression of HLA-DR and CD86. DEP+ LPS induced a bell-shape dose-response curve on the expression of all three markers, with a dose of 20 ng/mL DEP + 100 ng/mL LPS causing the largest increase in upregulation. When only the results of the LPS-responsive donors (5 out of 7 blood cord samples) were included, the effects described above become more pronounced.
Reference: Walczak-Drzewiecka et al. (2003, 188803) **Species:** Mouse **Cell Line:** C1.MC/C57.1 (C57) Mast Cells	Metal and Transition Metal Ions: Sr^{2+}, Ni^{2+}, Cd^{2+}, Al^{3+}, Pb^{2+} **Particle Size:** NR	**Route:** Cell culture, **Dose/Concentration:** 0.1- 5 µmol **Time to Analysis:** 10 min - 4 h	**B-Hex Mediator Release in Mast Cells:** Incubation with $SrCl_2$, $NiSO_4$, $CdCl_2$ or $AlCl_3$ resulted in a 2-5% release of B-hexoaminidase in mast cells. Incubation with a mixture of all these compounds induced a greater (11%) release in B-hexoaminidase, indicating there might be a additive effect. **Cell Viability:** Incubation of cells at concentrations and incubation time employed did not result in decrease in cell viability. **Antigen-Mediated Mediator Release in Mast Cells**: Al^{3+} and Ni^{2+} enhanced antigen-mediated release. 10-7 M $AlCl_3$ released 23% of B-hexoaminidase compared to antigen alone, which induced 11% release of B-hexoaminidase. Cd^{2+}, Sr^{2+} and Pb^{2+} enhanced antigen-mediated release to a lesser extent. Ni^{2+}, Al^{3+}, Sr^{2+} and Cd^{2+} depicted a dose-dependent relationship with antigen-mediated B-hexoaminidase release. **Antigen-Induced Protein Phosphorylation**: Addition of the antigen induced the anticipated phosphorylation of multiple proteins in C57 mast cells The presence of Ni^{2+} and Pb^{2+} mediated an increase in phosphorylation of several of the proteins and Al^{3+} mediated a decrease in phosphorylation of multiple proteins (specifically the 56 and 37 kD bands). **Antigen-Mediated Cytokine Secretion (IL-4):** At certain concentrations all tested metal and transition metal ions were able to induce IL-4 secretion or enhance antigen-induced IL-4 secretion in mast cells, but no dose-dependent relationship was established.

Study	Pollutant	Exposure	Effects
Reference: Whitekus et al. (2002, 157142) **Species:** Mouse **Cell Line:** RAW 264.7	DEP (light-duty, four-cylinder engine-4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 50 µg/mL **Time to Analysis:** Exposed to antioxidants 5 h. HO-1 western blot, determination of cellular GSH:GSSG ratios, carbonyl protein content, lipid hydroperoxides performed.	DEP significantly reduced the GSH:GSSG ratio. This effect was prevented by adding thiol antioxidants NAC or BUC. DEP increased lipid peroxide levels, but the addition of all antioxidants decreased these levels. DEP increased carbonyl groups. NAC, BUC, and luteolin reduced HO-1 expression.
Reference: Whitekus et al. (2002, 157142) **Species:** Mouse **Gender:** Female **Strain:** BALB/c **Age:** 6-8 wk **Weight:** NR	DEP (light-duty, four-cylinder engine-4JB1 type, Isuzu Automobile, Japan; standard diesel fuel) (extracts) **Particle Size:** 0.5-4 µm	**Route:** Inhalation **Dose/Concentration:** 200, 600, 2000 µg/m^3 **Time to Analysis:** Exposed 1 h/day, 10 days. Animals receiving OVA had 20 min OVA exposure after DEP exposure.	DEP+OVA dose-dependently increased IgE and IgG1, being more effective than the OVA-alone treatment. This effect was significantly suppressed by thiol antioxidants NAC or BUC. DEP+OVA increased carbonyl protein and lipid peroxide over OVA. NAC or BUC suppressed lipid peroxide and protein oxidation. No general markers for inflammation were observed.
Reference: Witten et al. (2005, 087485) **Species:** Rat **Gender:** Female **Strain:** F344 **Age:** 8 wk **Weight:** ~175 g	DEP (heavy-duty Cummins N14 research engine operated at 75% throttle) **Particle Size:** 7.234-294.27 nm	**Route:** Nose-only Inhalation **Dose/Concentration:** Low- 35.3 ± 4.9 µg/m^3, High-632.9 ± 47.61 µg/m^3 **Time to Analysis:** Exposed 4 h/day, 5 days/wk, 3 wk. Pretreated with saline or capsaicin.	There were no differences for substance P. The low-exposure group had significantly less NK1. DEP reduced NEP activity. Plasma extraversion dose-dependently increased and was greatest in capsaicin animals. Respiratory permeability dose-dependently increased. IL-1β was significantly higher for the low-exposure group. IL-12 was significantly lower in the capsaicin high-exposure group. TNF-α increased in the high-exposure group and capsaicin low-exposure group. High exposure induced particle-laden AMs in the lungs, perivascular cuffing consisting of mononuclear cells, alveolar edema and increased mast cell number. Neutrophil and eosinophil influx was not seen.
Reference: Wong et al. (2003, 097707) **Species:** Rat **Gender:** Female **Strain:** F344/NH **Age:** ~4 wk **Weight:** ~175 g	DEP (Cummins N14 research engine at 75% throttle) (EC- 34.93-601.67 µg/m^3, OC- 1.90-11.25 µg/m^3, Sulfates 0.94-17.96 µg/m^3, Na- 4.07-4.78 ng/m^3, Mg-0.60-0.86 ng/m^3, Ca- 5.05-10.66 ng/m^3, Fe- 3.17-6.44, Cr- 0.68-1.31 ng/m^3, Mn-0.11-0.22 ng/m^3, Pb- 0.97-1.24 ng/m^3) **Particle Size:** 7.5-294.3 nm	**Route:** Nose-only Inhalation **Dose/Concentration:** Low- 35.3 ± 4.9 µg/m^3, High-669.3 ± 47.6 µg/m^3 **Time to Analysis:** Exposed 4 h/day, 5 days/wk, 3 wk. Pretreated with saline or capsaicin.	DEP dose-dependently increased plasma extraversion, which was further increased by capsaicin. In the high-exposure group, particle-laden AMs (which were reduced by capsaicin), inflammatory cell margination, perivascular cuffing with subsequent mononuclear cell migration and dispersal, increased mast cells, and decreased substance P were all seen. NK-1R was downregulated in the low-exposure group and upregulated in the capsaicin-pretreated high-exposure group. NEP decreased significantly for both groups.

(2006, 096458) **Species:** Mouse **Gender:** Male **Strain:** ICR **Age:** 5 wk **Weight:** 25-28 g	Washed DEP (carbonaceous core), DEP-OC(extracted organic chemicals) and Whole DEP Particles collected from: 4JB1-Type, four-cylinder, 2.74 L, Isuzu diesel engine, while operated on standard diesel fuel at 200 g under a load of 10 torques. **Particle Size:** 0.4 µm (MMAD)	**Route:** IT Instillation **Dose/Concentration:** 50 µg/0.1L 1. Control- 0.1mL PBS 2. DEP-OC- 50 µg 3. Washed DEP- 50 ug 4. Whole DEP- 50 ug DEP-OC + 50 ug Washed DEP5. OVA- 1 µg = 6. DEP-OC- 1 µg + OVA 7. Washed DEP- 50 µg + OVA 8. Whole DEP- 50 µg DEP-OC + 50 µg Washed DEP + OVA **Time to Analysis:** All groups received OVA or PBS every 2 wk for 6 wk and the PM component or PBS once a week for 6 wk.	**BALF Cells**: DEP-OC + OVA caused a significant increase in PMN infiltration in the BALF compared to the control. Exposure to Whole DEP+ OVA caused PMN count to rise further. OVA alone DEP-OC +OVA, Washed DEP + OVA and Whole DEP + OVA all caused a significant increase in macrophages compared to the control. **Lung Histology**: Exposure to OVA, Washed DEP, DEP-OC and Whole DEP caused a slight increase in PMNs, mononuclear cells and goblet cell proliferation. Treatment with all three DEP groups + OVA caused a significant increase in mononuclear cells, PMNs and goblet cell proliferation. Whole DEP + OVA had the greatest impact. **Th1 and Th2 Cytokine Expression**: Washed DEP+OVA caused a significant increase in IFN-γ compared to control, whereas Whole DEP+OVA caused a significant decrease compared to control. No significant differences in IL-2 and IL-4 levels were seen among groups. DEP-OC+ OVA and Whole DEP+ OVA caused significant increases in IL-5 compared to control and compared to OVA Whole DEP+OVA caused significant increase in IL-13 compared to control **Eotaxin and MIP-1α Expression**: OVA increased eotaxin levels and DEP-OC+OVA caused a more significant increase in eotaxin. Whole DEP alone caused a significant increase in MIP-1α and Whole DEP+OVA caused an even greater increase in MIP-1α. **IgG1 Levels:** Exposure to DEP-OC+OVA caused an increase in IgG1 and exposure to Whole DEP+OVA caused greater elevation in IgG1 levels.
Reference: Yang et al. (2003, 087886) **Species:** Mouse **Gender:** Female **Strain:** B6C3F1 **Age:** 6-8 wk	DEP- SRM 1650 **Particle Size:** 0.5 µm (MMAD)	**Route:** IT Aspiration **Dose/Concentration:** 1, 5, or 15 mg /kg **Time to Analysis:** 3 times in 2 wk or 6 times in 4 wk.	**Toxicity of DEP Exposure**: DEP did not have a significant effect on body, liver or spleen weight. The highest dose of DEP caused an increase in lung weight and lung weight relative to body weight. None of the hematological parameters were significantly different in the mice exposed for 2 wk; in the 4 wk group there was a significant decrease in platelet counts in mice exposed to 15 mg/kg. **Exposure on Spleen IgM AFC:** DEP exposure for 2 wk induced a dose-dependent decrease in spleen AFC in response to sRBC immunization. Mice exposed to 15 µg/kg depicted a 35% reduction in total spleen activity. In the group exposed to DEP for 4 wk, the decrease in AFC was not significantly different than the control. **DEP Exposure on Spleen Cell Number/Lymphocyte Counts:** Exposure for 2 or 4 wk did not affect total number of nucleated splenocytes. DEP caused a 30% reduction in total T cells. The number of B cells were not significantly affected. **DEP Exposure on Spleen T-Cell Function:** (evaluated in 2 wk exposure group only) DEP induced a dose-dependent decrease in spleen cell proliferation to ConA. DEP did not affect spleen cell proliferation in response to anti-CD3 mAb. Production of IL-2 in response to ConA was reduced in a dose-dependent manner by DEP exposure. IFN-γ production was decreased by exposure to DEP. IL-4 production was not measured.

AM isolated then incubated. DEP treatments for up to 24 h.	**DEP-Induced ROS Production:** ROS was induced by DEP or eDEP and inhibited by eDEP with ANF or NAC. eDEP induction of ROS was time-dependent. wDEP or CB did not induce ROS. **DEP-Induced HO-1 Expression:** DEP- or eDEP-induced HO-1 expression was inhibited by ANF, NAC or SB203580. wDEP or CB did not induce ROS. DEP or eDEP exposure resulted in a 2.5- to 3-fold induction of HO-1 expression in uninfected AM. **eDEP-Modulated Cytokine Production:** eDEP exposure resulted in a time-dependent increase in LPS-stimulated IL-10 or TNF-α production, and both were inhibited by ANF or NAC. wDEP did not affect either. SOD pretreatment attenuated eDEP-upregulated HO-1 expression, inhibited IL-10, and reversed eDEP inhibition of IL-12. Znpp decreased IL-10.
Reference: Yin et al. (2003, 096127) **Species:** Rat **Gender:** Male **Strain:** Brown-Norway (BN/CrlBR) **Age:** NR **Weight:** 200-250 g	DEP = SRM 1650a L. monocytogenes **Particle Size:** NR	**Route:** Nose-only Inhalation (DEP); IT Instillation (Listeria) **Dose/Concentration:** 50 or 100 mg/m^3 (DEP); 100,000 bacteria per 500 µL sterile saline (Listeria) **Time to Analysis:** DEP exposure for 4 h. Bacterial inoculation. Sacrificed 3, 7 days post-exposure.	**Lymphocyte Population:** DEP-alone exposure increased total lymphocytes, T cells and T-cell subsets. Elevated cell counts in the combined exposure were DEP dose-dependent, with the 100 mg/m^3 treatment having significant increases in the cell number and CD8+/CD4+ ratio. **IL-2:** DEP exposure in noninfected rats at both doses increased IL-2 in the 24 h culture and decreased IL-2 in the 48 h culture. The increase in IL-2 at 3 days postinfection was not significant. DEP exposure increased IL-2Rα in response to ConA stimulation. DEP-treated infected rats had increases in ConA-inducible CD4+/IL-2Rα+ and CD8+/ IL-2Rα+. **IL-6:** IL-6 production was dose-dependent in DEP-treated uninfected rats and infected rats. The combined exposure produced less IL-6 than the DEP-alone or Listeria-alone treatments. **IFN-γ:** DEP decreased IFN-γ at 3 days post-exposure, but increased at 7 days post-exposure in a dose-dependent manner. Uninfected DEP-treated rats did not substantially respond to HKLM. HKLM-induced IFN-γ production is strongly inhibited at all tested DEP doses.
Reference: Zelikoff et al. (2003, 039009) **Species:** Rat **Gender:** Male **Strain:** F344 **Age:** 7-8 mo **Weight:** NR	CAPS (concentrated ambient $PM_{2.5}$ from New York City) S.pneumoniae **Particle Size:** 0.4 µm (MMAD)	**Route:** Nose-only Inhalation (CAPS); IT Instillation (S.pneumoniae) **Dose/Concentration:** CAPS: Study 1- Mean- 345 µg/m^3; 60-600 µg/m^3. ,Study 2- Mean-107 µg/m^3; 65-150 µg/m^3 (S.pneumoniae 2-4×10^7) **Time to Analysis:** Study 1: Uninfected rats exposed to air or CAPS for 3 h. Sacrificed 3, 24, or 72 h post-exposure or IT instilled 4, 24, 72, 120 h and sacrificed 4, 24, 72 h postinfection Study 2: Infection with bacteria. Exposed 48 h later to CAPS or filtered air for 5 h. Sacrifice 9, 18, 24, 72, 120 h post-exposure.	**Study 1:** CAPS did not effect cell numbers, viability, profiles, lavageable LDH activity, total protein, or total circulating WBC counts. Exposure to CAPs prior to infection significantly increased PMN and decreased lymphocytes. WBC levels returned to control levels by 4 h postinfection. CAPS had no effect on circulating monocyte values. CAPS significantly increased bacterial burdens at 24 h, but thereafter the burden decreased to below control levels. **Study 2:** In CAPS exposed rats, PMN decreased, Pam increased, and the cytokines TNF-α, IL-1β and IL-6 decreased. Lymphocytes and monocytes were unaffected. Bacterial burdens in CAP-exposed rats were about 10% greater than air controls at 9 h and >300% greater at 18 h. CAPS significantly increased the percent of affected lung area and severity of infection.

Study	Pollutant	Exposure	Effects
Reference: Zelikoff et al. (2002, 037797) **Species:** Rat **Gender:** Male **Strain:** Fischer 344 **Age:** 7-9 mo. **Weight:** NR	Ambient NYC PM Single transition metals of Fe, Mn, Ni Streptococcus pneumoniae **Particle Size:** NYC PM: $PM_{2.5}$ $Fe^{2+,}$ Mn^{2+}, Ni^{2+}: 0.4 µm (MMAD)	**Route:** Nose-only Inhalation, IT instillation (S. pneumoniae) **Dose/Concentration:** Single metals/NYC PM: 65-90 µg/m^3; 15-20×10^6 (S.pneumoniae) **Time to Analysis:** Infection/no infection followed by 5 h exposure to NYC PM or single transition metal. Sacrifice 4, 5, 9, 18, 24, and 120 h after exposure.	CAPs exposure to infected rats significantly increased pulmonary bacterial burdens of S. pneumo in a time-dependent manner. At 9 h, 18 h, 24 h, and 5 days after CAPs exposure, bacterial burdens were 10%, 300%, 70% and 30% above controls. Uninfected rats exposed to the single transition metals showed significant alterations in PMNs and lymphocytes values at 1 h post-exposure. Exposure to Fe of uninfected rats significantly increased superoxide anion production by pulmonary macrophages. Uninfected rats exposed to inhaled Fe significantly reduced B-lymphocyte proliferation at 48 h, but did not affect T-lymphocyte production. Inhaled Ni, for the uninfected, significantly decreased T-lymphocyte production at 18 h, and did not affect B-lymphocyte production. Inhalation of Fe by infected rats facilitated an increase in bacterial numbers while Ni inhibited bacterial clearance. Inhaled Fe by infected also significantly decreased PMNs and lymphocyte numbers by 35% and increased pulmonary macrophage numbers by 29% when compared to the air exposed group. Results demonstrated that inhalation of Fe altered innate and adaptive immunity in uninfected hosts, and both Fe and Ni reduced pulmonary bacterial clearance in previously infected rats.
Reference: Zhong et al. (2006, 093264) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 6-8 wk **Weight:** NR **Cell Line:** J774A.1, IFN-y-primed AMs, unprimed AMs	CAPs: Concentrated Air Particles (Boston, MA) Urban air particles (UAP) SRM1649 (Washington, DC) TiO_2 Carbon Black (CB) (Sigma, St. Louis, MO) Streptococcus pneumoniae: strain ATCC6303 **Particle Size:** UAP = NR; TiO_2/CB = NR; CAPs: ≤$PM_{2.5}$	**Route:** Cell Culture **Dose/Concentration:** NR, 100 µg/mL **Time to Analysis:** CAPs for 1 h; bacteria for 1 h. Binding measured 15 h after bacteria exposure. Ingestion measured 2 h after bacteria exposure. Rate and number of killed bacteria measured 2 h after bacteria exposure.	**Binding, Internalization and Killing of Bacteria:** CAPS significantly increased binding of bacteria by IFN-y-primed AMs, normal AMs and J774A.1. CAPS decreased internalization and absolute number of bacteria killed by macrophages of all types. The rate of killing of internalized bacteria was similar in the presence or absence of CAPs; however, CAPs did cause a decrease in the absolute number of bacteria killed by all three types of macrophages, due to the decrease in internalization. **Effects of other particles:** TiO_2 and CB had no effect on J774 binding or internalization of S. pneumo. TiO_2 and CB's effects on primed and unprimed AMs were not reported. Testing with UAPs, however, showed effects similar to those observed with CAPs. **Soluble components:** The soluble fraction of CAPs, especially iron, is responsible for decreased internalization.

Table D-5. Effects of the central nervous system.

Reference: Calderón-Garcidueñas et al. (2003, 156316) **Species:** Dog **Gender:** Male, Female **Strain:** Mixed breed **Age:** 7d-10 yr **Weight:** 349 ± 116g - 20 kg	Urban Air (Mexico City-high PM region, Tlaxcala- low PM region) (PM, Pb, volatile organic compounds, formaldehyde, acetaldehyde, mutagenic PM, alkane hydrocarbons, Ni, V, Mn, Cr, peroxyacetyl NO_4^{2-}, LPS, endotoxins) **Particle Size:** PM: 2.5, 10 µm	**Route:** Ambient Air Exposure **Dose/Concentration:** Mexico City: PM_{10}: 78 µg/m^3, $PM_{2.5}$: 21.6 µg/m^3, Pb in TSP: <0.4 µg/m^3 **Time to Analysis:** Dogs raised in house or outdoor-indoor kennel. Lifetime exposure.	Mexico City dogs had significantly greater apurinic and apyrimidic sites in the olfactory bulb and hippocampus. Histopathological changes in the respiratory and olfactory epithelium were greatest in Mexico City dogs. Mexico City dogs also had greater immunoreactivity than the controls for NF-κB, iNOS, cyclooxygenase-2, glial fibrillatory acidic protein, ApoE, amyloid precursor product and B-amyloid.

Reference	Pollutant	Exposure	Results
Reference: Campbell et al. (2005, 087217) **Species:** Mouse **Strain:** BALB/c **Age:** 7 wk	CAPs from Los Angeles, lacking reactive organic and H_2O soluble gases, O_3, NO_X, SO_X **Particle Size:** F+UF: <2.5 µm; UF: <0.18 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 20-fold concentration of near highway ambient air, avg UF concentration: 282.5 µg/m^3, avg F concentration: 441.7 µg/m^3 **Time to Analysis:** 4 h/day, 5 days/wk for 2 wk	Mice were challenged with OVA prior to exposure and 1 and 2 wk following exposure, and then brains were assayed. F+UF and UF exposure increased NF-κB DNA binding in brain. TNF-α increased with F+UF. IL-1α increased with UF and F+UF. This suggests a possible link between PM exposure and neurodegenerative disease processes.
Reference: Che et al. (2007, 096460) **Species:** Rat **Strain:** SD **Gender:** Male and Female **Age:** 9 wk **Weight:** 190-220 g	Gasoline exhaust (collected from 1996 Guangzhou passenger car with Dongfeng Gasoline Series 155 kw engine and no exhaust catalytic converter fuelled with 90-octane Pb-free gasoline from China Petroleum). **Particle Size:** NR	**Route:** IT Instillation **Dose/Concentration:** 5.6, 16.7, or 50.0 L/kg, final volume 0.3 mL/rat **Time to Analysis:** 1/wk for 4 wk; 24 h post-instillation.	A dose-dependent increase was observed in brain DNA damage starting at 5.6 L/kg. Increase in lipid peroxidation and carbonyl protein was also observed at 50 L/kg. Decrease in brain SOD occurred at all exposures. GPx activity was unchanged with exposure. This suggests an association between gasoline exhaust and oxidative damage to the brain.
Reference: Kleinman et al. (2008, 190074) **Species:** Mouse **Gender:** Male **Strain:** ApoE$^{-/-}$ **Age:** 6 wk **Weight:** NR	CAPs (Los Angeles, CA) (OC, EC = ~50%; sulfate, nitrate ~11%) **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** High dose: Mass concentration- 114.2 µg/m^3, Low dose: Mass concentration: 30.4 µg/m^3 **Time to Analysis:** 5 h/day, 3days/wk, 6 wk; 24 h postexposure.	Activated AP-1 dose-dependently increased. Activated NF-κB significantly increased with the high CAPs dose. GFAP (which represented activated astrocytes) and activated JNK significantly increased with the low CAPs dose.
Reference: Liu et al. (2005, 088650) **Species:** Rat **Strain:** Wistar **Gender:** Male **Age:** 8 wk	CAPs from Taiyuan, China **Particle Size:** <2.5 µm	**Route:** IT Instillation **Dose/Concentration:** 0, 1.5, 7.5, or 37.5 mg/kg, final volume 0.2 mL/rat **Time to Analysis:** 24 h	In the brain, SOD and CAT activity were significantly decreased at the 2 highest doses; GSH levels were significantly decreased at the highest dose. This suggests an association between PM exposure and oxidative damage mediated by prooxidant/antioxidant imbalance or high levels of free radicals.
Reference: Sirivelu et al. (2006, 111151) **Species:** Rat **Gender:** Male **Strain:** Brown Norway **Age:** 12-13 wk	CAPs from Grand Rapids, MI **Particle Size:** <2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** 500 µg/m^3 **Time to Analysis:** 8h; assayed at 24-h PE	**PVN:** CAPs alone or with OVA increased NE. **MPA:** CAPs increased Da when treated with OVA while no changes in NE, 5-HIAA and DOPAC were observed. **Arcuate nucleus:** OVA sensitization increased NE levels. **OB:** CAPs and OVA increased NE levels, but no changes in Da, DOPAC, or 5-HIAA were observed. **Other areas:** No differences in other areas of hypothalamus, substantia nigra, or cortex were observed. CAPs alone or with OVA increased serum corticosterone. These results suggest that CAPs can cause region-specific modulation of neurotransmitters in brain and that the stress axis may be activated causing aggravation of allergic airway disease.
Reference: Veronesi et al. (2005, 087481) **Species:** Mouse **Strain:** ApoE$^{-/-}$ or C57Bl/6 **Age:** Young adults	CAPs from Tuxedo, NY **Particle Size:** <2.5 µm	**Route:** Whole-body Inhalation **Dose/Concentration:** Average daily concentration 113 µg/m^3 **Time to Analysis:** 6 h/day, 5days/wk for 4 mo	CAPs-exposed ApoE$^{-/-}$ mice had an 29% reduction in TH-stained neurons and a 8% increase in GFAP staining compared to air-exposed ApoE$^{-/-}$. No differences were see in C57 mice. The results suggest that ApoE$^{-/-}$ mice, characterized by increased brain oxidative stress, are susceptible to PM-induced neurodegeneration.

Reference	Pollutant	Exposure	Results
Reference: Win-Shwe et al. (2008, 190146) **Species:** Mouse **Gender:** Male **Strain:** BALB/c **Age:** 7 wk **Weight:** NR	DEP (Nanoparticle-rich - NPDE; 81-diesel engine, steady-state condition, 5 h/d, 2000rpm, 0 Nm) (CO, CO_2, NO, NO_2, SO_2) **Particle Size:** 26.21 ± 1.50 nm (diameter)	**Route:** Whole-body Inhalation **Dose/Concentration:** 148.86 ± 8.44 μg/m^3 **Time to Analysis:** 5 h/day, 5 days/wk, 4 wk. Some mice ip injected with lipoteichoic acid (LTA) 1×/wk, 4 wk. Morris water maze behavioral test: 3 days acquisition, 2 day probe trial.	Mice in the LTA+NPDE group had significantly longer mean escape latencies, indicating impaired acquisition of spatial learning. NPDE directly increased NR1 and TNF-α. LTA+NPDE increased NR2A, NR2B, and IL-1β, however LTA was primarily responsible for the increases.
Reference: Zanchi et al. (2008, 157173) **Species:** Rat **Gender:** Male **Strain:** Wistar **Age:** 45 days	ROFA from Universidade de São Paulo, Brazil **Particle Size:** 1.2 ± 2.24 μm (MMAD)	**Route:** Intranasal Instillation **Dose/Concentration:** 20 μg/10 μl saline **Time to Analysis:** 30 days	Exposed rats had increased lipid peroxidation in striatum and cerebellum. This could be reversed with N-acetylcysteine treatment. ROFA treatment altered motor activity shown by decreased general exploration and peripheral walking, and was not prevented by NAC. Results suggests that chronic ROFA induces behavioral changes and brain oxidative stress.

Reference: Tsukue et al. (2002, 030593) **Species:** Mouse **Strain:** C57/BL **Gender:** Females, male and female offspring **Age:** 6 wk, 70 days post natal (offspring)	DE: generated by light-duty, 4-cyl Isuzu diesel engine at 1500 rpm. **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** 0.3, 1.0 or 3.0 mg DEP/m^3 **Time to Analysis:** Exposed 12 h/day, 7 days/wk for 4 mo. Some females sacrificed immediately following exposure. Remainder mated with unexposed males. Parameters measured in offspring at postnatal day 70.	DE-exposed females had decreased uterine weight at 4 mo. Offspring had decreased body weight at 6 and 8 wk of age. Decreased rate of good nesting construction (3 mg/m^3). AGD decreased In males (30 and 70 days old). Organ weight decreased in females and female crown to rump length decreased.
Reference: Ueng et al. (2004, 096199) **Species:** Mouse **Gender:** Female **Strain:** Wistar **Age:** 21days **Cell Line:** MCF-7	ME: generated from a Yamaha Cabin motorcycle 2-stroke 50-cc engine and variable venture carburetor **Particle Size:** NR	**Route:** Intraperitoneal Instillation. Cell Culture. **Dose/Concentration:** IP: 1, 10, 50 µg/ml Cell Culture: 0.01, 0.1, 1, 10, 50, 100 µg/ml **Time to Analysis:** IP: 1/day for 3 days and sacrificed on 24 day. Cell Culture: 3, 24, 30, 48 h and 2 days.	10 mg/kg +E2 induced anti-estrogenic uterine effects and antiestrogenic with in vitro (MCF-7 cells) E2 screen.
Reference: Veras et al. (2008, 190493) **Species:** Mouse **Gender:** Male, Female **Strain:** BALB/c **Age:** 20 days, newborns **Weight:** NR	PM (downtown São Paulo, Brazil near crossroads with high traffic density, 67% $PM_{2.5}$ comprises air pollution) **Particle Size:** 2.5 µm (diameter)	**Route:** Open-Top Chamber **Dose/Concentration:** $PM_{2.5}$- 27.5 µg/m^3; NO_2- 101 µg/m^3; CO- 1.81 µg/m^3; SO_2- 7.66 ppm **Time to Analysis:** 20 days-old mice maintained in filtered or nonfiltered chamber until 60 days-old. Offspring maintained in respective chambers until 21 days-old. Offspring mate at 60 days-old. Females euthanized 18th GD.	Fetal weight and maternal blood space volume and surfaces declined in the groups exposed to nonfiltered air. Fetal capillary surfaces were greater in nonfiltered air groups. There was a significant gestational effect on maternal:fetal surface ratios with values declining significantly in groups exposed during pregnancy to nonfiltered air. The total oxygen diffusive conductance of the intervascular barrier increased significantly during pregestational exposure to nonfiltered air. Mass-specific conductance increased during pregestational and gestational periods of exposure to nonfiltered air.
Reference: Veras et al. (2009, 190496) **Species:** Mouse **Gender:** Male, Female **Strain:** BALB/c **Age:** 20 days **Weight:** NR	PM (São Paulo, Brazil; near crossroads with high traffic density) (Al, Ca, Cu, Fe, K, Na, Ni, P, Pb, S, Si, Ti, V, Zn, C) **Particle Size:** 2.5 µm (diameter)	**Route:** Open-Top Chamber **Dose/Concentration:** Mean: Non-filtered- 27.5 µg/m^3, Filtered- 6.5 µg/m^3 **Time to Analysis:** 20 days-old mice maintained in filtered or non-filtered chamber. Allowed to mate at 60 days. 2 generation model.	Ambient air pollution extended the estrus cycle, which reduced the number of cycles. Antral follicles decreased. Mating time increased and fertility and pregnancy indices decreased. The mean post-implantation loss rate increased, which was influenced by both pre- and post-gestational exposure. Fetal weight decreased and was also influenced by pre- and post-gestational exposure, which exhibited a significant interaction.
Reference: Watanabe (2005, 087985) **Species:** Rat **Gender:** Female (pregnant), Offspring- male **Strain:** F344/DuCrj **Age:** 7 days of gestation - parturition (females), 96 days (offspring) **Weight:** 240-262 g (offspring)	DE (309cc engine, Model NFAD50, Yanmar Diesel Co., Osaka, Japan, 1800rpm, 45% load) (PM, NO_2) **Particle Size:** 90% <0.5 µm	**Route:** Inhalation **Dose/Concentration:** High dose total group: PM- 1.71 µg/m^3, NO_2- 0.79 ppm; Low dose total group: PM- 0.17 µg/m^3, NO_2- 0.10 ppm **Time to Analysis:** Pregnant rats exposed gestational day 7 to delivery 6 h/day. 5 groups: high dose total DE, high dose PM, NO_2 filtered, low dose total DE, low dose PM, NO_2 filtered, clean air control. Offspring sacrificed day 96 after birth.	All groups had significantly less daily sperm production than the control. PM and NO_2 in DE decreased spermatogenia but was not significant, however the high dose PM filtered group achieved significance. Pachytene cells, spermatids, and Sertoli cells were lower in all groups compared to the control.

Reference: Yauk et al. (2008, 157164) **Species:** Mouse **Strain:** C57BL/6 x CBA F1 hybrid **Gender:** Male **Age:** 7-9 wk	HEPA-Filtered air (PM removed) and ambient air at 2 sites: -2 km from two integrated steel mills -1 km from major highway on Hamilton Harbor Components: Metals 3.6 ± 0.7 µg/m^3 TSP 9.4+17 µg/m^3 **Particle Size:** NR	**Route:** Ambient Air Exposure **Dose/Concentration:** NR **Time to Analysis:** Parameters measured 3, 10 wk, or 10 + 6 wk recovery following exposure.	10+6 wk exposure induced increased ESTR mutations in sperm DNA of exposed v filtered. No testicular DNA adducts seen in exposed males. At 3 wk DNA increased adducts seen in lungs of exposed males, not in filtered males. Mutations were PM dependent, and gas-phase independent.
Reference: Yokota et al. (2009, 190518) **Species:** Mouse **Gender:** Female (pregnant), Male (offspring) **Strain:** ICR **Age:** NR **Weight:** NR	DE (2369-cc diesel engine, Isuzu Motors, Ltd., Tokyo, Japan; 1050 rpm, 80% load, commercial light oil) **Particle Size:** NR	**Route:** Inhalation. Pre-natal Exposure **Dose/Concentration:** DE: 1.0 mg/m^3; CO: 2.67 ppm, NO_2: 0.23 ppm, SO_2: <0.01 ppm **Time to Analysis:** Pregnant mice exposed 8 h for 5 days from GD 2-17. Mothers and pups kept in clean room. Pups weaned on PND 21 then transported to Tokyo University of Science. 2wk acclimation. Exposed 12 h light/dark cycle. Activity monitor with infrared ray sensor measured spontaneous motor activity (SMA), 10 min intervals 2 days. After behavioral test, mice decapitated.	Prenatal DE exposure decreased SMA in the male offspring. DE decreased locomotor activity during the light phase. Dopamine levels in the striatum and nucleus accumbens did not change, but HVA concentrations decreased in DE-exposed mice.
Reference: Yoshida et al. (2006, 156170) **Species:** Mouse **Strain:** ICR, C57Bl/6J or DDY **Gender:** Pregnant Females, Male fetuses **Age:** 14 days of gestation (fetuses), 2-13 days of gestation (pregnant females)	DE(generated from a 4-cyl., 2300 cc diesel Isuzu engine at 1050 rpm and 80% load). **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** 0.1 mg DEP/m^3 **Time to Analysis:** Exposure on 2-13 days of gestation. Parameters measured on 14 days of gestation.	Responses to exposure showed strain-related variations with ICR as the most sensitive followed by C57 and ddY as the least sensitive. MIS mRNA expression, a factor in male gonadal differentiation, was significantly decreased in the ICR and C57 strains. Ad4BP/SF-1 expression was significantly decreased in the ICR strain only.
Reference: Yoshida et al. (2006, 097015) **Species:** Mouse **Strain:** ICR **Gender:** Pregnant females and male offspring **Age:** 2-16 days postcoitum (pregnant females), 28 days (male offspring)	DE: generated by 4Jb1-type, light duty 4-cylinder Isuzu diesel engine using standard diesel fuel at 1500 rpm. **Particle Size:** NR	**Route:** Whole-body Inhalation **Dose/Concentration:** 0.3, 1.0 or 3.0 mg DEP/m^3 **Time to Analysis:** Pregnant females exposed 12 h/days, 7 days/wk from 2-16 days postcoitum. Offspring sacrificed on postnatal day 28.	NOAEL 0.3 mg DEP/m^3. DE exposure induced increased reproductive gland weight (two higher doses) in male mice. mRNA decreases in aromatase and 3 µ-hD (3.0 mg DEP/m^3). No change in sex ratio. Two higher doses induced significant increased reproductive organ weights. Male pup weight Increased at PND 28. Increased serum T was observed in pups exposed to 1.0mg DEP/m^3. Serum T positively correlated with DSP, testis weight, steroid enzyme mRNA.
Reference: Yoshida et al. 2004 (2004, 097760) **Species:** Mouse **Gender:** Female (pregnant), Offspring- male **Strain:** ICR **Age:** 4, 6 wk **Weight:** NR	DE **Particle Size:** NR	**Route:** Inhalation **Dose/Concentration:** 6wk-old males, embryos: 0.3, 1.0, 3.0 mg DEP/m^3, Pregnant mice: 0.1, 3.0 mg DEP/m^3 **Time to Analysis:** 6 wk-old males: Exposed 12 h/day, 6 mo. 1 mo clean air exposure. Pregnant mice: Exposed 2-13 p.c. 8 h/day. Male embryos: Exposed 2-16 p.c. Examined at 4 wk-old.	**6wk-old Males:** In the seminiferous tubules, DE dose-dependently caused degenerative and necrotic changes, desquamation of the seminiferous epithelium, and loss of spermatozoa. Spermatogenesis was still inhibited after a 1m clean air exposure. **Pregnant Mice:** Ad4BP/5F-1 and MIS mRNA significantly and dose-dependently decreased in male fetuses exposed to DE. **4wk-old Male Newborns:** Tissue weight of the testis and accessory reproductive glands were significantly greater in DE-exposed mice. Blood testosterone concentration was 8X higher than the control at 1.0 mg DEP/m^3. No significant differences occurred for testosterone synthetase mRNA.

Table D-7. Mutagenic/genotoxic effects in bacterial cultures.

Reference: Binkova et al. (2007, 156273) **Species:** Salmonella (±S9 (rat liver)) **Cell Line:** Calf thymus DNA	PM (Prague, Košice, Sofia, Czech Republic; summer, winter) (organic extracts) **Particle Size:** Diameter: <10 µm	**Route:** Cell Culture **Dose/Concentration:** 100 µg EOM/mL **Time to Analysis:** PM collected 24 h daily 3 mo, extracted. 24 h incubation BaP, c-PAH, EOM, with or without S9. 32P-Postlabeling 4 h. Autoradiography 1-24 h.	DNA adducts in EOM treatments were greater with S9 than without. Positive correlations were found between the amount of DNA adducts and the PAH content (notably BaP) in the EOM treatment.
Reference: Brits et al. (2004, 087397) **Species:** S. typhimuriam **Strain:** TA98 ± S9 (Ames); TA104 recN2-4 and TA104pr1 (Vitotox) **Cell Line:** Human whole blood (Comet, MN assays)	PM (Flanders, Belgium; urban, rural, industrial sites) (organic extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 2.5, 5, 10, 20m^3 air equivalents/mL **Time to Analysis:** Air samples extracted. Ames assay 48 h. Vivotox test. Comet assay 24 h. MN assay.	**Ames:** S9 induced mutagenicity of all extracts from all areas in a dose-dependent manner. Without S9, only extracts from the urban and industrial areas were mutagenic at the highest dose. **Vitotox:** Extracts were toxic at the highest dose. **Comet:** Significant DNA damage in the extracts was seen and enhanced by S9. **MN:** A dose-response relationship was seen in the urban extracts for increased micronucleated binuclear cells.
Reference: Brown et al. (2005, 095919) **Species:** S. typhimuriam **Strain:**TA98 **Cell Line:** Rat hepatoma H4IIE	PM (New Zealand, summer, winter) (extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 9.7-20.8 µg/m^3 (summer), 21.8-61 µg/m^3 (winter) **Time to Analysis:** Air samples collected 15 days, extracted. Ames test: Bacteria growth 12 h, incubated 24 h. Hepatoma bioassay: 24 h incubation 2x. EROD assay.	Generally, the mutagenic rate was positively correlated to PM_{10}, as well as PAH and BaP. PM_{10} levels were higher and more mutagenic in winter than summer.
Reference: Bunger et al. (2006, 156303) **Species:** Salmonella typhimuriam **Strain:** TA98, TA 100	DEP (diesel fuel (DF), low-sulfur diesel fuel (LSDF), rapeseed oil methyl ester (RME), and soybean oil methyl ester (SME)) (SOF-soluble organic fractions) **Particle Size:** Total particulate matter (no OCC) (gh-1): Mean DF- 4.0 ± 0.2; 2.8 ± 0.5; 1.8 ± 0.0; 3.4 ± 0.2; 1.2 ± 0.1	**Route:** Cell Culture **Dose/Concentration:** Log 2 dilutions of extracts: 1.0, 0.5, 0.25, 0.125 **Time to Analysis:** SOF extracted 12 h. Plates incubated 48 h.	**No OCC:** Without oxidation catalytic converter (OCC), DF extract produced the highest number of revertant colonies at all load modes in both TA98 and TA100 ± S9. RME, SME, and LSDF extracts caused lower or no mutagenic effects, seen especially at partial load modes and idle motion. **OCC:** With OCC, all extracts reduced the number of revertant colonies in TA98 and TA100 ±S9 at partial load modes B, C, and D. At load mode A (rated power), there was an increase of the number of revertant colonies in all assays -S9, significant for extracts from RME (TA98, TA100) and SME (TA98). S9 lowered frequency of mutations. At load mode E (idling), number of revertant colonies of DF extracts increased ±S9.
Reference: Bunger et al. (2007, 156305) **Species:** Salmonella typhimuriam **Strain:** TA98, TA 100	Diesel engine emissions (DEE)—rapeseed oil (RSO) and rapeseed methyl ester (RME, biodiesel), natural gas derived synthetic fuel (GTL), and diesel fuel (DF) (SOF- soluble organic fractions) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Log 2 dilutions of extracts: 1.0, 0.5, 0.25, 0.125 **Time to Analysis:** SOF extracted 12 h. Plates incubated 48 h.	Compared to DF, RSO significantly increased mutagenic effects of particle extracts (i.e., revertants) by 9.7-59 in TA98 and by 5.4-22.3 in TA100. (mRSO, RSO with lowered viscosity and fuel preheating in tank, produced highest number of revertant colonies in both strains ±S9.) RSO fuels condensates had 13.5 times stronger mutagenicity than DF. RME extracts had moderate but significantly higher mutagenic response in TA98 +S9 and TA100 -S9. Effects of GTL did not differ significantly from DF.

Reference: de Kok et al. (2005, 088656) **Species:** S. typhimurium **Strain:** TA98 (with and without rat liver S9) **Cell Line:** Salmon testis DNA	TSP (Total suspended particulate , Maastricht, The Netherlands; PM_{10} and $PM_{2.5}$ from 6 urban locations with different traffic intensities.) (organic extracts) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Mutagenicity assay: 2.5, 9, or 18m^3 sampled air in 100 µL DMSO; DNA adduct assay: 5 µL DMSO containing PM_{10} or TSP from equivalent 50m^3 sampled air. $PM_{2.5}$ concentration equivalent to 35m^3 sampled air. **Time to Analysis:** Mutagenicity assay: Cells incubated 1 h with extracts. DNA adduct assay: DNA incubated 4 h with extracts.	Overall, the direct mutagenicity and DNA reactivity of $PM_{2.5}$ extracts were higher compared to PM_{10} and TSP. S9 generally reduced mutagenic activity in TA98 but increased reactivity to Salmon testis DNA. Total PAH and total carcinogenic PAH levels correlated with the mutagenicity of TSP and the S9-mediated mutagenicity of $PM_{2.5}$. Neither transition metal composition nor radical generating capacity of PM correlated with mutagenic potential. Total PAH and carcinogenic PAH levels from PM_{10} and $PM_{2.5}$ correlated with direct and S9-mediated DNA adducts; for TSP these levels correlated with direct DNA reactivity only.
Reference: DeMarini et al (2004, 066329) **Species:** Salmonella **Strain:** TA98, TA98NR, TA98/1, 8-DNP6, YG1021, YG1024, TA100	A-DEP and forklift DEP (SRM 2975) DEP (EOM) **Particle Size:** 0.4 µm (mean diameter)	**Route:** Cell Culture **Dose/Concentration:** 0, 0.25, 0.5, 1.0, 2.0 EOM µg/plate **Time to Analysis:** DEPs sonicated 20min. Centrifuged 10 min. Organic material extracted and concentrated. Ames assay. Incubated 3 days.	A-DEPs were more mutagenic in both TA98 and TA100 than SRM 2975. There was 22× more PAH-related and 8-45× more nitroarene-related activity.
Reference: El Assouli et al. (2007, 186914) **Species:** S. typhimuriam **Strain:** TA98 (±S9)	PM (Jeddah, Saudi Arabia; 11 sites, urban, winter) (organic extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 2.5, 50, 100 µg/plate; EOM range: 6-40 µg/m^3 **Time to Analysis:** 24 h air samples, extracted. Refluxed 18-24 h. GC-MS. Comet assay. 48 h incubation. Ames assay.	PAHs varied from 0.83 to 0.18 ng/m^3. Only 2 locations of heavy petrol driven cars showed strong genotoxic responses. A correlation existed between DNA damage and the amount of pollutants and PAHs. Toxicity and mutagenicity occurred only in the presence of S9. Only 3 of the 11 sites exhibited moderate mutagenic activities.
Reference: Endo et al. (2003, 097260) **Species:** S. typhimuriam **Strain:** YG1024 (±S9)	PM (Tokyo, Japan; winter) (organic extracts) **Particle Size:** Diameter: >12.1 - 0.06> µm; Bimodal mass concentration: 1-2 µm	**Route:** Cell Culture **Dose/Concentration:** 2.5, 5, 10 µL; 0.30 - 22.76 µg/m^3 **Time to Analysis:** Air samples collected, extracted. 90 min pre-incubation. 48 h incubation.	Mutagenicity tests showed dose-response relationships that were higher without S9 and increased with decreasing size.
Reference: Erdinger et al. (2005, 156423) **Species:** S. typhimurium **Strain:** TA98. TA100, TA98NR	PM (Baden-Württemberg, Germany; urban, 8 locations, glass fiber filters) (organic extracts) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 0.25, 2.5, 5, 12.5, 25 m^3/plate **Time to Analysis:** Standard Ames test protocol followed.	Extracts were mutagenic in all strains evaluated. No significant difference in response with or without metabolic activation. Activity in TA98NR suggests that the mutagenicity correlates with concentrations of air pollutants such as NO_X.
Reference: Iba et al. (2006, 156582) **Species:** S. typhimuriam **Strain:** TA98, TA100 (±S9 (rat liver))	PM (wood smoke (WS) (New Jersey) and cigarette smoke (CS) (Tobacco Research and Health Institute, University of Kentucky) (organic extracts) **Particle Size:** 10 µl aliquots of organic extracts	**Route:** Cell Culture **Dose/Concentration:** 62.5, 12.5 µg TPM equivalent/plate **Time to Analysis:** Incubation, shaking 25 min. Agar added. 48 h incubation. Rat lung explants incubated 18 h. 12 h incubation with treatments.	WS and CS were equally mutagenetic to TA98, but CS was 3-fold more mutagenetic to TA100 than WS. CS induced CYP1A1 in the explants, but WS did not.
Reference: Liu et al. (2005, 097019) **Species:** S. typhimurium **Strain:** YG1024, YG1029 **Cell Line:** Chinese hamster lung V79 cells	DEP extract (DP), gasoline engine exhaust particulate extract (GP), diesel exhaust SVOC extract (DSVOC), gasoline engine SVOC extract (GSVOC), NIST SRM 1650a **Particle Size:** Gasoline PM: 0.554 mg extract (mg PM)-1; Diesel PM: 0.363 mg extract (mg PM)-1	**Route:** Cell Culture **Dose/Concentration:** 1.48, 4.44, 13.3, 40, 120, 360, 1080 µg/plate **Time to Analysis:** 30 min preincubation. 48 h (YG1029). 66 h (YG1024). Overnight preincubation 20 h.	**Mutations:** All samples induced mutations in both strains. The increase was highly significant and dose-dependent. Response with S9 was generally greater than without S9. PM extract was more mutagenic than SVOC extract. **DP, GP, and GSVOC:** Dose-response was seen for DNA damage and micronuclei induction. GP, GSVOC and SRM 1650a were stronger inducers of micronuclei than DP.

Reference: Matsumoto et al. (2007, 187020) **Species:** S. typhimuriam **Strain:** TA98, TA100 (±S9)	APM (airborne particulate matter) APE (airborne particulate extracts) (Hokkaido, Japan; residential) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Crude APE: 979mg/m^3 air (CALUX BaP Equivalent (BaPEq)), 21 mg/m^3 air (CALUX TCDD Equivalent (TCDDEq)); Cleaned APE: 7.87 mg/m^3 air (CALUX BaPEq), 0.614 mg/m^3 air (CALUX TCDDEq) **Time to Analysis:** Air samples collected, extracted. Preincubation with S. typhimuriam. 3, 24 h exposure in CALUX assay. RNA extracted from mice 6 days after last application.	Most of the CALUX BaPEq for crude APE was derived from PAH-like compounds, as suggested by the CALUX BaPEq of cleaned APE accounting for 0.80% of CALUX BaPEq for crude APE. CALUX TCDDEq showed TCDD and similar compounds to have a low contribution. The TA100 strain was more mutagenic to APE, with and without S9. S9 increased mutagenicity in both strains.
Reference: Pastorkova et al. (2004, 087431) **Species:** S. typhimuriam **Strain:** TA98, YG1041 (±S9)	PM (EOM) (Plzeň, Prague, Ústí, Zďár - Czech Republic) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** TA98 (4 doses): 20-200 µg/plate, YG1041 (4 doses): 4-20 µg/plate **Time to Analysis:** Collected 24 h every 18th day, Oct-Mar, 1999-2003. Extracted. Ames assay. 70 h incubation.	Significant dose-response effects in mutagenic potency of EOM occurred. Prague, one of the most polluted cities, had the highest mutagenicity values. Increasing time-trends were observed in the TA98 ± S9 mutagenicity and PAH concentrations.
Reference: Rivedal et al. (2003, 097684) **Species:** S. typhimurim **Strain:** TA100, TA98, TA100NR, TA98NR, TA98/1,8-DNP6	DEP (SRM 1650)(organic extracts) (fractionated into PAH, nitro-PAH, dinitro-PAH, aliphatics, polar fraction) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Ames: 300, 600 DEP/plate; Gap junction: 100, 200 µg/mL DEP **Time to Analysis:** Extracted 16 h. Fractionated. Ames assay. Gap junction intracellular communication: exposed 1-6 h. Western blot.	TA100 was the most mutagenic without S9 activation. GJIC was dose- and time-dependently inhibited. The polar fraction was the most potent inhibitor. Nitro-PAH and dinitro-PAH were the most responsive fractions in the Ames assay.
Reference: Seagrave et al. (2003, 054979) **Species:** Salmonella **Strain:** TA98, TA100	Compressed natural gas (CNG) emissions (heavy-duty vehicles): High emitter (HE), Normal emitter (NE), New technology (NT) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** PM (mg/mi)- NE- 7.0, NT- 5.0, HE- 406; Recovered PM (mg/mi)- NE-1.26, NT- 0.71, HE- 57.1; Recovered SVOC- NE- 58, NT- 26.4, HE- 227.5 **Time to Analysis:** Samples collected in filters 7x/day over several days. Recovered PM, recovered SVOC extracts combined. Ames assay.	All three CNG emissions were mutagenic in both strains. Mutagenicity was reduced by S9 in TA100 but not in TA98. Activity ranking in both strains was HE>NE>NT.
Reference: Sharma et al. (2007, 156975) **Species:** S typhimurium **Strain:** TA98, YG1041, YG5161 **Cell Line:** Human A549 lung epithelial cells	PM (airborne, 4 sites: an oven hall and receiving hall in a waste incineration plant; heavy-traffic street; background; Mar-June 2005) **Particle Size:** 2.5 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 0.25 mg/ml **Time to Analysis:** Samples taken over 7-16 days. A549 cells incubated 24 h. Comet and microsuspension assays performed.	**DNA damage:** Samples from all four sites induced DNA damage in the comet assay with the street samples more damaging than the oven hall sample. **Mutations:** Microsuspension assay was used to assess mutagenic activity. No mutagenic activity was observed for any of the non-polar fractions from any sample sites. The moderately polar fractions were all mutagenic, except for the oven hall sample, only when S9 was added. Comparatively, the polar and crude fractions were mutagenic without metabolic activation, suggesting a direct mutagenic effect.
Reference: Song et al. (2007, 155306) **Species:** S. typhimurium **Strain:** TA98, TA100 **Cell Line:** Rat fibrocytes L-929 cells	PM (soluble organic fraction (SOF) extracts from diesel engines using fuels blended with ethanol by volume: E0 - base diesel fuel; E5 - 5%; E10 - 10%; E15 - 15%; E20 - 20%) **Particle Size:** Density (g/cm^3): E0- 0.8379; E5- 0.8349; E10- 0.8324; E15- 0.8301; E20- 0.8279	**Route:** Cell Culture **Dose/Concentration:** Ames Assay: 0.025, 0.05, 0.1 mg/plate; Comet Assay: 0.125, 0.25, 0.5, 1.0 mg/mL **Time to Analysis:** Samples extracted 24 h. Ames and comet assays performed	All PM extracts induced higher mutational response in TA98 (3- to 5-fold increase over spontaneous) than in TA100 (2-to 3-fold increase). The highest brake specific revertants (BSR) ±S9 in both strains occurred with E20 and lowest BSR was in E5 (except in TA98 -S9). E0 and E20 caused more significant DNA damage (similar in effect) than the other extracts. Damage was dose-dependent but variable with increasing ethanol volume.

Reference	Pollutant	Exposure	Effects
Reference: Zhang et al. (2007, 157186) **Species:** S. typhimurium **Strain:** TA98, TA100 **Cell Line:** A549	Gasoline engine exhaust (GEE) Methanol engine exhaust (MEE) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** MTT Assay- 0.05-0.8 GEE or MEE L/ml; MN Assay- 0.025, 0.05, 0.1, 0.2 GEE or MEE L/ml; Comet Assay- 0.025, 0.05, 0.1, 0.2, 0.4 GEE or MEE L/ml; Ames Assay- GEE: 0.625, 1.25, 2.5, 5.0, 10, 20 L/plate; MEE: 0.3125, 0.625, 1.25, 2.5, 5.0, 10, 20 L/plate **Time to Analysis:** Organic extracts from GEE and MEE. MTT assay- 24 h incubation, followed by 2 or 24 h incubation, followed by 4 h incubation. MN assay- 24 h incubation. Comet assay. Ames assay- 72 h incubation.	**Mutagenicity:** GEE was mutagenic in TA98 but not TA100, -S9 at 10 and 20 L/plate and +S9 at ≥1.25 L/plate. Mutagenicity was higher with S9 than without at 0.625-10 L/plate and a dose-response was reported. MEE had no effect in either strain. **MN:** GEE significantly and dose-dependently induced MN. MEE had no significant effect at any dose. **DNA damage:** GEE significantly induced DNA damage at all doses compared to controls. MEE had no effect at any dose.
Reference: Zhao et al. (2004, 100972) **Species:** Rat **Gender:** Male **Strain:** SD **Age:** NR **Weight:** ~200 g **Cell Line:** S. typhimurium YG1024 (±S9)	DEP (SRM 2975) DEPE (SRM 1975) Carbon black (CB) (Elftex-12 furnace black, Cabot, Boston, MA) **Particle Size:** NR	**Route:** IT Instilled. Cell Culture. **Dose/Concentration:** DEP or CB: 35mg/kg; S9: 25, 50, 100, 200 µg/plate; Cytosolic protein: 20, 40, 80, 160 µg/plate; Microsomal protein: 5, 10, 20, 40 µg/plate **Time to Analysis:** Rats instilled. Sacrificed 1, 3, 7 days post-exposure. S9, cytosolic, microsomal fractions prepared from lung homogenates. Ames assay: 72 h incubation.	DEP and CB-exposed lung S9 time-dependently decreased 2-aminoanthracene (2-AA) mutagenicity. Metyrapone and α-napthoflavone inhibited the S9-activation of 2-AA in DEP and CB exposed rats. Lung S9 increased the mutagenicity of DEPE but not of DEP or CB. Liver S9 reduced DEPE dose-dependently. CYP2B1 and CYP1A1 activated DEPE, with CYP2B1 being more effective.
Reference: Zhao et al. (2006, 100996) **Species:** S. typhimuriam **Strain:** YGL024 (±S9)	DEP (SRM 2975) DEPE (SRM 1975) Aminoguanidine (AG) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** NR **Time to Analysis:** Lung S9 obtained from rats used in in vivo experiment. Ames test. Modified microsuspension assay. All assays in duplicate plates. Repeated 3x.	AG significantly lowered 2-aminoanthracene mutagenic activity of DEP or DEPE-exposed lung samples, with DEP being lowered the most.

Table D-8. Mutagenicity and genotoxicity data summary: In vitro and in vivo.

Reference	Particle	Exposure	Effects
Reference: Abou Chakra et al. (2007, 098819) **Species:** Human **Gender:** Male, Female **Age:** 6-13 yr and Adults **Participant Characteristics:** Non-smokers **Cell Line:** HeLa S3 cells	PM (3 French metropolitan cities: Urban $PM_{2.5}$ and PM_{10} from "Residential Sector," "Proximity Sector," "Industrial Sector") (organic extracts) **Particle Size:** 2.5, 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 200 µL organic extract; 20 µL aphidicoline **Time to Analysis:** 24 h	Seasonal variation was observed with genotoxic effects being greater in winter. $PM_{2.5}$ was more active than PM_{10} extracts. Samples from the "Proximity Sector" (downtown area with heavy traffic) exhibited the strongest genotoxic responses.
Reference: Arrieta et al. (2003, 096210) **Species:** Rat **Cell Line:** Hepatoma (H4IIE) **Species:** Mouse **Cell Line:** Hepatoma H1l1.1c2	PM (El Paso, Texas; Juarez, Chihuahua, Mexico; Sunland Park, New Mexico) (organic extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** EROD test: 0.03, 0.17, 0.34, 0.50, 0.68, 4.96, 9.93 extract equivalents (m^3 air); Luciferase: 0.17, 0.51, 1.26, 5.01 extract equivalents (m^3 air) **Time to Analysis:** 24 h	EROD activity declined at higher extract amounts, but luciferase activity was not inhibited. Cytotoxicity occurred only at extract equivalents to 0.47 m^3 air. PAH concentration increased with PM mass.

Reference	Particle	Exposure	Effects
Reference: Bao et al. (2007, 097258) **Cell Line:** Human-hamster hybrid (AL)	DEP (organic extracts) (SRM 2975) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 10, 20, 50, 100 µg/mL **Time to Analysis:** Phagocytosis inhibitors: Exposed 24 h with or without cytochalasin B or ammonium chloride. Cytotoxicity: 24, 48 h incubation. Mutations: Exposed 24 h. 5-7 days culture. Incubated additional 7-8 days.	The nucleus of DEP-treated cells was condensed and shrunken compared to controls. DEPs accumulated in cells, disrupting the mitochondrial cristae, and were lodged in large cytoplasmic vacuoles. DEP produced minimal toxicity. CD59 locus mutations dose-dependently increased but decreased when simultaneously treated with cytochalasin B or ammonium chloride.
Reference: Carvalho-Oliveria et al. (2005, 077898) **Species:** T. pallida; A. cepa	PM (Sao Paulo, Brazil; spring, bus strike and non-strike days) (organic extracts) **Particle Size:** 2.5 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** Strike day: 47.32 µg/m^3; Non-strike day: 43.01 µg/m^3 **Time to Analysis:** 8 h. 24 h recovery. A. cepa roots induced 5 days. Exposed 30 h. Fixed 24 h.	Element concentrations, sulfur and BTEX decreased on the strike day. Micronuclei decreased in T. pallida during the strike. Toxicity measured in A. cepa was not significant, but higher on strike days.
Reference: Dybdahl et al. (2004, 089013) **Species:** Human **Cell Line:** A549	DEP (SRM 1650) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 10, 50, 100, 500 µg DEP/mL **Time to Analysis:** 2, 5, 24 h incubation.	DEP induced dose-dependent increases of IL-1α, IL-6, IL-8, TNF-α. The cytokines increased 4-18-fold at the highest dose. Cell viability did not decrease. Comet tail length increased at 100 and 500 µg/mL for 2, 5, 24 h.
Reference: Gabelova et al. (2007, 156458) **Species:** Human **Cell Line:** Hepatoma Hep G2	PM (PRG-SM, PRG-LB, Košice, Sofia; winter, summer) (organic extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 5-150 µg/mL **Time to Analysis:** 2, 24, 48 h	Cell viability significantly decreased in the 24, 48 h exposure groups compared to the 2 h exposure group. DNA migration significantly dose-dependently increased at most concentrations. In general, oxidative DNA damage did not significantly increase.
Reference: Gabelova et al. (2007, 156457) **Species:** Human **Cell Line:** Hepatoma Hep G2 cell line	PM_{10} (Prague (Czech Republic), Ko˘sice (Slovak Republic) and Sofia (Bulgaria); urban, winter, summer) (organic extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 5 -150 µg/ml **Time to Analysis:** 24 h DNA adduct formation. 2 h Comet assay. Oxidative DNA damage measured by Fpg-sensitive sites.	Total DNA adducts ranged from ~60 to 200 adducts per 108 nucleotides. Extracts also produced approximately the same levels of strand breaks. Results suggested that the genotoxic potential of ambient air was at least 6-fold greater in the winter compared to summer. No substantial difference was reported for oxidative DNA damage induced by summer vs. winter samples.
Reference: Gong et al. (2007, 091155) **Species:** Human **Cell Line:** Microvascular endothelial (HMEC)	DEP (aggregates, exhaust 4JB1-type LD,274 1,4-cylinder Isuzu diesel engine, 10 torque load, cyclone impactor, dilution tunnel constant volume sampler) **Particle Size:** <1 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 5, 15, 25 µg/mL **Time to Analysis:** Cells treated with DEP, ox-PAPC (oxidized 1-palmitoyl-2-arachidonyl-sn-glycero-3-phosphorylchlorine), DEP+ox-PAPC	HO-1 expression was dose-dependent and greatest with the DEP+ox-PAPC treatment. DEP significantly dose-dependently upregulated or downregulated a number of genes and was shown to have a synergistic effect with co-treatment of ox-PAPC. The most varying genes were significantly enriched for EpRE, inflammatory response, UPR, immune response, cell adhesion, lipid metabolism, apoptosis and protein folding genes.
Reference: Greenwell et al. (2003, 097478) **Species:** Rat **Cell Line:** Epithelial fluid; icosahedral bacteriophage φX174-RF DNA	PM (South Wales, UK) (urban, industrial) **Particle Size:** Coarse diameter: 10-2.5 µm, Fine diameter: 2.5-0.1 µm	**Route:** Cell Culture **Dose/Concentration:** Urban mean: 18.7 ± 4.7 mg/day; Industrial mean: 22.6 ± 2.5 mg/day **Time to Analysis:** 24 h air samples 4-11 days. Substrates vortexed 1 h, suspended 4 h, centrifuged 1 h. Oxidation assay.	Industrial PM was more bioreactive than urban PM. Coarse fractions had greater oxidative potential and bioreactivity than fine fractions.
Reference: Gu et al. (2005, 195923) **Species:** Hamster **Strain:** Chinese **Cell Line:** Lung fibroblast (V79)	DPM (1980 model General Motors 5.7-L V-8 engine) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 25, 50, 100, 150 µg/mL; 10 µg DPM in 10 µg in DPPC/mL; 10 µg DPM in 10 µg DMSO/mL **Time to Analysis:** Chromosomal aberration: 24 h incubation. Treated 24 h. Incubated again 24 h. MN assay: 24 h treatment. Gene mutation: 24 h treatment. Cells replated. 7 days expression times. Staining at 8, 10 days.	DPM significantly and dose-dependently increased aberrant cells at 25-100 µg/mL. DPM increased MN formation dose-dependently. Mutant frequencies were not significant and showed no dose-dependent trends. DPM was toxic to cells at the highest concentration.

Reference	Particle	Exposure	Effects
Reference: Gualtieri et al. (2005, 097841) **Species:** Human **Cell Line:** A549	TD (Tire debris, generated by rotating new vehicle wheel against a steel brush, significant component of PM_{10}) (organic extracts) **Particle Size:** 10-80 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 50, 60, 75 µg/mL **Time to Analysis:** Particles extracted 6 h. Cells subcultured every 3-4 days. After 24 h, TD treatments 24, 48, 72 h.	A time- and dose-dependent inhibitory effect on the reduction of MTT was seen. Mortality increased dose-dependently and was significantly greater than the controls. DNA strand breaks increased significantly in a dose-dependent manner. A significant cell cycle block in the G1 phase with a consequent decrease in the cell number in the S and G2/M phases was seen. Exposed cells had a modified morphology.
Reference: Gutierrez-Castillo et al. (2006, 089030) **Species:** Human **Cell Line:** A549	$PM_{2.5}$ and PM_{10} (4 monitoring stations in Mexico City: (1) downtown high auto traffic, (2) two industrial areas with high levels of auto traffic and low vegetation, (3) medium-traffic residential area) (winter, spring , 4 sampling days in each period) (aqueous and organic extracts) **Particle Size:** 2.5 or 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 0.05, 0.07, 0.1m^3/ml equivalents $PM_{2.5}$; 0.82, 1.25, 1.63m^3/ml equivalents PM_{10} **Time to Analysis:** 48 h	Higher amounts of water-soluble metals were found in samples collected during winter. Water-soluble extracts increased DNA damage 1.7-fold over the background. Similar results were observed with organic extracts. In general, $PM_{2.5}$ extracts had greater genotoxic potential than PM_{10} extracts, and water soluble fractions form both particle sizes were more genotoxic than the corresponding organic extracts.
Reference: Izawa H et al. (2007, 190387) **Cell Line:** NA	DEPE (4JB-1 Isuzu 4-cylinder direct-injection 2740cc diesel engine; 1500 rpm, 10 kg/m load) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** DEP: Ah-1 experiment- 111, 55.5, 27.8, 13.9, 6.9, 3.5, 1.7 µg/mL; Foods, polyphenols experiment- 27.8 µg/mL **Time to Analysis:** DEPE incubated 2 h for dioxin toxicity measurement. Absorbance at 405 nm measured. Food, polyphenol inhibitory effects: food extract or polyphenol solution added to cytosol solution, shaken 5 min. DEPE added, shaken 5 min. 2 h incubation. Absorbance at 405 nm measured.	The dioxin toxicity equivalent was 6,479 ± 58 ng DEQ/g of DEP. The absorbance showed a sigmoid curve and dose-dependently increased from 6.9 to 27.8 µg DEP/mL. The Ginkgo biloba extract significantly inhibited AhR activation significantly more than the other foods, and was followed by green tea, onions, and garlic. Quercetin and myricetin dose-dependently inhibited AhR activation. Ginkgolides A and B had weak inhibitory effects and resveratol was the weakest.
Reference: Jacobsen et al. (2008, 156597) **Species:** Mouse **Cell Line:** FE1-MutaTM lung epithelial cells	DEP (SRM 1650b) Carbon black (CB) (Printex 90) **Particle Size:** DEP: 18-30 nm; CB: 14 nm; Agglomerates in suspensions: DEP Peaks- 249 nm, CB Peaks- 476 nm	**Route:** Cell Culture **Dose/Concentration:** 37.5, 75 µg/mL **Time to Analysis:** 8 repeated 72 h incubations.	**Mutagenicity:** The 75 µg/mL dose was significantly increased compared to the 37.5 µg/mL dose. Linear regression showed a significant increasing trend by increasing exposure. There was no change in the total cell numbers. **ROS:** ROS production increased in DEP-treated cells after 3 h of exposure. CB-treated cells showed a dose-dependent increase.
Reference: Karlsson et al. (2004, 198976) **Species:** Human **Cell Line:** Fibroblasts; calf thymus DNA with human liver microsomes or rat liver S9	PM (urban dust particles, SRM 1649) (extracted with DCM, acetone, DMSO, water) (Fe 3% w/w, Ti 0.32% w/w, V 0.04% w/w, Mn 0.03% w/w, Cu 0.025% w/w) **Particle Size:** <10 µm (mean diameter)	**Route:** Cell Culture **Dose/Concentration:** 0.1, 1.0, 10, 100 µg/cm^2 **Time to Analysis:** Fibroblasts exposed 24 h. Comet assay. Calf thymus incubated 2 h with microsomes or S9. 32P-labelled.	DNA damage increased dose-dependently, and a significant amount of DNA-damaged cells had particle interactions. DNA damage induced by the insoluble particle core significantly increased after each extraction. Native particles were more genotoxic than those extracted with DMSO, DCM and water, but not with acetone or hexane. DMSO extracts had the most adduct-forming PACs, and water extracts had the most oxidizing substances.
Reference: Karlsson et al. (2005, 086392) **Species:** Human **Cell Line:** A549	PM (subway station, urban street) Subway particles: O_2, Fe (Fe from Fe_3O_4) Street particles: Fe from Fe_2O_3 **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** Comet: 5, 10, 20, 40 µg/cm^2; 8-oxodG: 10 µg/cm^2 **Time to Analysis:** 4 h.	Both PM types induced concentration-dependent DNA damage, but subway particles were more potent. Subway particles caused more 8-oxodG formation and oxidation of dG, the latter of which was inhibited by deferoxaminemesylate. Oxidation from subway particles was due to nonsoluble, redox active substances, and soluble substances from street particles.
Reference: Karlsson et al. (2006, 156625) **Species:** Human **Cell Line:** A549; monocytes from heparinized whole blood	PM (wood- old, modern boiler; pellets-pellets burner, electrical ignition; tire-road simulator studded, friction tires; Street- busy street, Stockholm; Subway-platform near street) **Particle Size:** 2.5, 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 40 µg/cm^2 **Time to Analysis:** Cells grown 24 h. Comet assay. Monocytes incubated 10 days. Macrophages incubated 18 h.	All particles tested caused DNA damage, but there was no significant difference between the size fractions. Subway particles were the most genotoxic. The urban street particles were the most potent inducers of the cytokines. On the Teflon filters, PM_{10} was somewhat more potent than $PM_{2.5}$.

Reference	Particle	Exposure	Effects
Reference: Kubátová et al. (2004, 087986) **Species:** Monkey **Cell Line:** African green kidney COS-1 (CV-1 cells with origin-defective SV40 mutants) (±S9)	PM (DE from diesel bus, wood smoke (WS) from chimney, hardwood smoke) (organic extracts) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 25, 50, 100, 200 µg/mL; 50mg of each material used for all experiments **Time to Analysis:** 24 h cytotoxicity. 2 h SOS chromotest.	WS had significantly increased cytotoxicity in fractions of 25-250°C, and DE in nonpolar fractions of 250 and 300°C and polar fractions of 50°C. The cytotoxicity of DE PM nonpolar fractions corresponded to increased concentrations of PAHs. WS was not genotoxic and DE was genotoxic in midpolarity fractions (50-250°C). Genotoxic response was not increased after S9 activation.
Reference: Landvik et al. (2007, 096722) **Species:** Mouse **Cell Line:** Hepatoma Hepa1c1c7 cells	DEP extracts (DEPE in the paper) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 10, 20, 30, 50, 70 µg/mL **Time to Analysis:** 24 h	50 and 70 µg/mL DEPE did not induce DNA fragmentation but did cleave caspase 3 to a minor extent.
Reference: Mehta et al. (2008, 190440) **Species:** Human **Cell Line:** A549	PM (SRM 1949a) **Particle Size:** ≤ 0.18 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 0, 50, 100, 200, 400 µg/mL **Time to Analysis:** Cell culture and cell viability assay: PM treatment 24 h. 10 days incubation. Host cell reactivation assay: pGL3-luciferase plasmid UV irradiated 20 min. PM treatment 24 h. 16 h transfection. 24 h PM incubation. DNA repair synthesis assay: PM treatment 24 h. Proteinase K treatment 30 min. supf mutagenesis assay: PM treatment 24 h. PM culture 60 h. DNA extracted. Overnight incubation of transformed bacteria.	PM reduced colony-forming ability and repair synthesis capacity was proportional to the PM concentration. PM dose-dependently decreased HCR capacity and decreased more than TSP. PM induced cyclobutane dimmers and pyrimidine<6-4>pyrimidones mutations in UV-irradiated supf.
Reference: Meng and Zhang (2007, 198963) **Species:** Rat **Gender:** Male **Strain:** Wistar Kyoto **Age:** NR **Weight:** Mean: 230g; Range: 200-250g **Cell Line:** AMs from treated rats	PM (Baotou, Wuwei, China) (normal weather, dust storms, Mar 1-31) (organic extracts, water soluble fractions) **Particle Size:** 2.5 µm	**Route:** Cell Culture **Dose/Concentration:** AM: 0, 33.3, 100, 300 µg/mL; Water-soluble: 0, 75, 150, 300 µg/mL; Organic extracts: 0, 25, 50, 100 µg/mL; Mass concentration normal day: 68.49 ± 28.83 µg/m^3; Mass concentration dust storm day: 221.83 ± 69.89 µg/m^3 **Time to Analysis:** 24 h; cultures 4 h.	OC, NH_4^+, NO_3^- were higher in normal weather $PM_{2.5}$. SO_4^{2-}, Ca^{2+} were higher in dust storm $PM_{2.5}$. Fe, Al, Ca, Mg were 5x higher in dust storm $PM_{2.5}$. Cell viability reduced in a concentration-dependent manner, with normal weather being slightly more cytotoxic. DNA damage was dose-dependently induced, with normal weather and organic extracts showing the greatest damage.
Reference: Motta et al. (2004, 198953) **Species:** Hamster **Strain:** Chinese **Cell Line:** Epithelial liver, ovary	PM (Catania, Sicily; spring) (organic extracts) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 0.60, 1.21, 2.42, 4.85, 9.70, 19.40 µg/mL; 0.78, 1.56, 2.12, 6.25, 12.50, 25.00 µg/mL **Time to Analysis:** 24 h	The treatment was only slightly cytotoxic at the highest dose. DNA damage and aberrant cells generally increased with dose. No effect was seen in the Chinese hamster ovary cells without metabolic activation.
Reference: Oh and Chung (2006, 088296) **Cell Line:** A549 (Comet), CHO-K1 (CBMN), H4IIE (EROD-microbiassay)	Crude extract (CE) DEP and fractions of CE of DEP (organic extracts: F1 - organic bases, F2 - organic acids, F3 - aliphatic, F4 - aromatic, F5 - slightly polar, F6 --moderately polar, F7 - high polar) **Particle Size:** Diameter: <2.5 µm, 87.71%, 2.5-10 µm, 3.87%, >10 µm, 8.42%	**Route:** Cell Culture **Dose/Concentration:** 100 µg/mL **Time to Analysis:** DEP generated, extracted. Comet assay- 24 h incubation, CE, DEP exposed 24 h. MN assay- cultured 24 h, 4 h treatment, growth medium incubation 20 h. EROD-microbioassay- 48 h.	**DNA damage:** CE significantly increased the amount of DNA damage in A549 cells with and without SKF-525A, a CYP450 inhibitor, and in CHO-K1 cells. It significantly increased MN formation ±S9 compared to controls. **Organic Extracts:** Organic base (F1) and neutral (F3-F7) fractions of CE of DEP significantly induced DNA damage without SKF-525A compared to controls. Adding SKF-525A completely inhibited damage caused by F3, F4, F6 and F7 but kept the effect of F1 similar to that without SKF and only partially inhibited that of F5. F2 did not induce DNA damage with or without SKF. All fractions except F6 induced MN formation ±S9.

Reference	Particle	Exposure	Effects
Reference: Poma et al. (2006, 096903) **Species:** Mouse **Cell Line:** RAW 264.7	PM (L'Aquila, Italy; urban); air samples collected weekly basis Jan-Mar 2004. Carbon black (CB) **Particle Size:** 2.1-0.43 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 1, 3, 10 µg/cm^2 **Time to Analysis:** Cells cultured 48 h. Treatment 48 h. MN assay: 44 h incubation, 28 h incubation.	PM and CB dose-dependently reduced cell proliferation and induced micronuclei. PM and CB also reduced cellular metabolism of the macrophages and induced significant amounts of apoptosis. PM produced more micronuclei than equally-weighted CB.
Reference: Roubicek et al. (2007, 156929) **Species:** Human **Cell Line:** A549	PM (Mexico City from an industrial area with high-traffic and a medium-traffic residential area) (aqueous or organic extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 1.25, 1.63, 2.5 m^3/ml equivalents of PM_{10} **Time to Analysis:** Cells treated 24 h followed by 48 h incubation with cytochalasin B. Micronuclei frequency determined.	Water and organic extracts induced a significant dose-dependent increase in the micronuclei frequency. After doses of PM from different regions were normalized for mass differences, the genotoxic potency was higher for samples from the industrial area.
Reference: Salonen et al. (2004, 187053) **Species:** Mouse **Cell Line:** RAW 264.7	PM (Vallila, Finland; busy traffic site; spring, winter) **Particle Size:** <10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 15, 50, 150, 500, 1000 µg/mL of RPMI **Time to Analysis:** 24 h	PAHs decreased from winter to spring. TNF-α dose-dependently increased and was higher in spring samples. IL-6 generally increased in spring but not in winter. NO dose-dependently increased and was higher in winter. Cell viability generally decreased but there were no consistent potency differences between the samples. Generally, proinflammatory activity, cytotoxicity and IL-6 were associated with the insoluble PM fractions. Polymyxin B inhibited IL-6 and TNF-α. ·OH and 8-hydroxy-2'-deoxyguanosine dose-dependently increased and were higher in the spring and winter, respectively.
Reference: Seaton et al. (2005, 198904) **Species:** Human **Cell Line:** A549	PM (3 busy London underground (LU) stations and cabs) (LU dust in $PM_{2.5}$ samples: iron oxide 64-71%, chromium 0.1-0.2%, manganese 0.5-1%, copper <0.1-0.9%; respirable dust samples: 1-2%) **Particle Size:** Diameter: <2.5 µm, 10 µm, Median diameter: 0.4 µm	**Route:** Cell Culture **Dose/Concentration:** Assays: 1, 10, 50, 100 µg/mL **Time to Analysis:** 8, 24 h.	PM_{10} caused less LDH release, IL-8 stimulation and free radical activity than LU dust particles that contained $PM_{2.5}$. Chelation had little effect on PM_{10} soluble components.
Reference: Sevastyanova et al. (2007, 156969) **Species:** Human **Cell Line:** HepG2 cell line, embryonic lung diploid fibroblasts (HEL), or acute monocytic leukemia cells (THP-1)	PM_{10} (Prague, Czech Republic; Ko˘sice; Slovak Republic; Sofia, Bulgaria) (urban, summer, winter) (organic extracts) **Particle Size:** 10 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 10-100 µg/ml **Time to Analysis:** 24 h	DNA adducts were observed in all cell types evaluated. Highest adduct levels were observed in HepG2 cells, followed by HEL and THP-1 cells. A correlation between DNA adduct levels and carcinogenic PAH content was observed in HepG2 cells at 50 µg/ml.
Reference: Shi et al. (2003, 088248) **Species:** Human **Cell Line:** A549	PM (Düsseldorf, Germany, July-Dec.) Weekly samplings July-Dec 1999. **Particle Size:** Fine diameter: <2.5 µm; Coarse diameter: 10-2.5 µm	**Route:** Cell Culture **Dose/Concentration:** Fine: 0.57-2.49 mg; Coarse: 0.66-1.89 mg; Concentration: 0.57 mg/mL **Time to Analysis:** NR	Coarse and fine particles generated ·OH, but coarse particles had significantly higher ·OH formation as well as 8-hydroxy-2'-deoxyguanosine formation. 8-hydroxy-2'-deoxyguanosine and ·OH had a significant correlation.
Reference: Skarek et al. (2007, 096814) **Species:** Rat **Cell Line:** Modified hepatoma H4IIE.luc; SOS: E. coli PQ37 (±S9)	PM (urban: Ústí and Laben, Karviná; background: Červenohorské sedlo, Košetice - Czech Republic; July) (organic extracts, TSP); GP (gas phase). 24 h samples July 2002 **Particle Size:** <2.5 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** SOS: 8, 4, 2, 1 m^3/ml; Dioxin: TSP+GP- 8, 1.33, 0.22, 0.04 m^3/ml, $PM_{2.5}$+GP: 4, 0.66, 0.11, 0.02 m^3 ml-1 **Time to Analysis:**. SOS chromotest: 22 h incubation. Dioxin toxicity test: 24 h exposure.	The urban areas had a much greater level of carcinogenic PAHs and overall number of PAHs than the background areas. Significant genotoxic activity was only detected at TSP+GP without S9 from urban areas. $PM_{2.5}$+GP had lower dioxin activity at the urban areas, but similar levels of toxicity were seen for both treatments in the background areas.
Reference: Song et al. (2007, 155306) **Species:** S. typhimurium **Strain:** TA98, TA100 **Cell Line:** Rat fibrocytes L-929 cells	PM (soluble organic fraction (SOF) extracts from diesel engines using fuels blended with ethanol by volume: E0 - base diesel fuel; E5 - 5%; E10 - 10%; E15 - 15%; E20 - 20%) **Particle Size:** Density (g/cm^3): E0- 0.8379; E5- 0.8349; E10- 0.8324; E15- 0.8301; E20- 0.8279	**Route:** Cell Culture **Dose/Concentration:** Ames Assay: 0.025, 0.05, 0.1 mg/plate; Comet Assay: 0.125, 0.25, 0.5, 1.0 mg/mL **Time to Analysis:** 24 h	All PM extracts induced higher mutational response in TA98 (3- to 5-fold increase over spontaneous) than in TA100 (2-to 3-fold increase). The highest brake specific revertants (BSR) ±S9 in both strains occurred with E20 and lowest BSR was in E5 (except in TA98 -S9). E0 and E20 caused more significant DNA damage (similar in effect) than the other extracts. Damage was dose-dependent but variable with increasing ethanol volume.

Reference	Particle	Exposure	Effects
Reference: Ueng et al. (2005, 097054) **Species:** Human **Cell Line:** Lung epithelium CL5 (cancerous), BEAS-2B, WI-38 normal lung fibroblast	MEP (Yamaha cabin motorcycle 2-strok 50-cc engine) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 1, 10, 100, 200 µg/mL **Time to Analysis:** microarray analysis. RT-PCR: 2 h. ELISA: 12 h incubation. Centrifuged 24 h post-treatment. Bioactivity: 12 h incubation. Centrifuged 24 h post-treatment. Medium replaced 48 h post-incubation. Fibroblasts determined 96 h post-incubation. Time response studies: 3-48 h treatment. Concentration response studies: 6 h treatment.	**Drug Metabolism Array Study:** MEP increased CYP1A1, CYP3A7 and UGT2B. **Cytokine Array Study:** MEP increased fibroblast growth factor (FGF)-6, FGF-9, IL-1α, IL-22 and vascular endothelial growth factor (VEGF)-D mRNA. **Oncogene, Tumor Suppressor, Estrogen Signaling Pathway:** MEP increased fra-1, c-src, SHC, p21, COX7RP, and decreased p53 and Rb expression. **RT-PCR:** MEP increased CYP1A1, CYP1B1, IL-6, IL-11, IL-1α, FGF-6, FGF-9, VEGF-D, fra-1 and p21. **Concentration and Time Responses:** Concentration and time-dependent increases occurred for FGF-9, IL-1α, IL-6, IL-11, but decreased time-dependently after 6 h exposure. **BEAS-2B Cells:** MEP had concentration-dependent increases on CYP1A1 and CYP1B1 but did not affect anything else. **Peroxide, MEP+NAC, WI-38 Cells:** MEP increased peroxide production. The MEP+NAC treatment reduced MEP-elevated levels of IL-1α, IL-6, FGF-9, VEGF-D to control levels. Fibroblasts increased in WI-38 cells.
Reference: Umbuzeiro et al. (2008, 190491) **Species:** Salmonella typhimurium **Strain:** TA98, YG1041 (+/- S9)	PM (urban; São Paulo, Brazil- Cerqueira César street station, Ibirapuera park station) (winter- June 17, 18; average temperature: 16ºC) (EOM) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** Cerqueira César: UPM- 156 µg/m^3, EOM- 57.7 mg/total UPM; Ibirapuera Park: UPM- 32 µg/m^3, EOM- 41.7 mg/total UPM; Salmonella assay- 0.5, 1, 5, 10, 50, 100 UPM equiv/plate (µg) **Time to Analysis:** Organic extraction 20 h. PAH fractionation.	The TSP and EOM were similar for both sites. The PAH fraction had very low mutagenicity for the Cerqueira César sample in the YG1041 strain and no mutagenicity for the Ibirapuera sample. Nitro-PAH and oxy-PAH had similar mutagenetic activities from both samples. S9 decreased mutagenicity in nitro-PAH but was increased in oxy-PAH. DNA adduct levels were dose-dependent and not different between the two sites.
Reference: Upadhyay et al. (2003, 097370) **Species:** Human **Cell Line** A549	PM (Dusseldorf, Germany) (Particles contain carbon (19.70%), hydrogen(1.4%),nitrogen (<.05%), oxygen(14.12%), sulfur (2.09%), ash (63.24%)) (Ionizable metals concentrations (ppm): Co(103), Cu(48),Cr(104),Fe(14,521), Mn(21.3), Ni(1,519),Ti(131), V(2,767) **Particle Size:** NR	**Route:** Cell Culture **Dose/Concentration:** 1, 5, 25, 100 µg/cm^2; 10, 25, 50, 100 µg/cm^2 **Time to Analysis:** 1, 4, 8, 12, 24 h.	PM induced dose- and time-dependent reductions in ds-DNA due to the formation of DNA-SB. The soluble component caused higher DNA damage. Apoptosis and DNA fragmentation increased dose-dependently. ΔΨm decreased dose-dependently in control cells, but not in cells with Bcl-xl overexpression. PM caused activation of caspase 9. Pretreatment with iron chelators or a free radical scavenger reduced PM-induced DNA-SB formation, DNA fragmentation, caspase 9 activation, and weakened ΔΨm reductions.
Reference: Valavanidis et al. (2005, 096432) **Cell Line:** NR	PM (TSP: high volume pumps, Athens; DEP: 2.0L engine GM Astra; GEP: 1.6L passenger vehicle Ford; Wood smoke soot: domestic fireplace exhaust chimney; PM_{10}: high volume sampling system, Athens; $PM_{2.5}$: high volume cascade impactor (Anderson) system **Particle Size:** >10.2 - <0.41 µm (diameter)	**Route:** Incubation **Dose/Concentration:** 20, 40 mg/5mL **Time to Analysis:** PM incubated with H_2O_2 and 2'-deoxyguanosine (dG). Stored 3-7 days at -20°C.	PM generated ·OH by a Fenton reaction, which is increased by the addition of EDTA but inhibited by deferoxamine. PM dose-dependently induced dG hydroxylation and 8-hydroxy-2'-deoxyguanosine formation. Transition metals Ni, V, Co, Cr that are capable of redox cycling electron producing ROS were found in the PM samples.
Reference: Xu and Zhang (2004, 097231) **Species:** Human **Cell Line:** A549	PM (Taiyuan, Beijing; Nov-Feb) (Taiyuan: coal-fume pollution; Beijing: coal-fume and vehicle exhaust) **Particle Size:** 2.5 µm (diameter)	**Route:** Cell Culture **Dose/Concentration:** 5, 50, 200 µg/mL **Time to Analysis:** 12-24 h	Taiyuan had a significantly higher daily $PM_{2.5}$ average than Beijing. It was shown that the smaller the particulate diameter, the higher the concentration of BaP and Pb. A dose- and time-response relationship was seen in DNA fragmentation.

Reference	Design & Methods	Concentrations[1]	Effect Estimates (95% CI)
Reference: Park et al. (2005, 057331) **Period of Study:** Nov 2000-Oct 2003 **Location:** Greater Boston area, MA	**Outcome:** Change in HRV (SDNN, HF, LF, LFHFR) **Mean age:** 72.7 yr **Study Design:** Cross-sectional **N:** 497 adult males living in the Greater Boston, MA area	**Pollutant:** $PM_{2.5}$ **Averaging Time:** 4 h 24 h 48 h **Mean (SD):** 11.4 (8.0) **Range:** 6.45-62.9 **Copollutant:** O_3, Particle number count, BC, NO_2, SO_2, CO	**PM Increment:** 8 µg/m^3 **Percent change (95% CI):** 48h mean $PM_{2.5}$: 20.8% decrease in HF (95% CI: 4.6%, 34.2%) 18.6% increase in LFHFR (4.1%, 35.2%). **Notes:** Subjects were monitored during a 4-min rest period between 8 a.m. and 1 p.m. Modifying effects of hypertension, IHD, diabetes, and use of cardiac/anti-hypertensive medications also examined. Linear regression analyses. This subject group is from the VA Normative Aging Study. The 4-h averaging period was most strongly associated with HRV indices. The PM effect was robust in models including O_3. The HRV change per IQR increase in $PM_{2.5}$ were larger in subjects with hypertension (n = 335) IHD (n = 142), and diabetes (n = 72). In addition, those who did not use calcium-channel blockers had a greater decline in LF associated with each IQR increase in $PM_{2.5}$ than did those who did use calcium channel blockers. IQR increases in 48h mean BC concentration were also associated with adverse changes in HRV, suggesting traffic pollution may be particularly toxic.

There were consistent positive but largely nonsignificant coefficients for TNF-α, sVCAM-1, and sICAM-1, but not fibrinogen, IL-6sR, or D-dimer. The authors found inverse associations for erythrocyte Cu, Zn-SOD with these pollutants and other PM size fractions (0.25-2.5 and 2.5-10 µm). Inverse associations of GPx-1 and MPO with pollutants were largely nonsignificant. Indoor associations were often stronger for estimated indoor EC, OCpri, and PN of outdoor origin than for uncharacterized indoor measurements. There was no evidence for positive associations with SOA.

Summary: Positive significant or marginally significant associations between $PM_{2.5}$ and cerebrovascular disease at Lag 0 Peripheral vascular disease at Lags 0 and 2 Ischemic heart disease at Lag 2 Heart rhythm disturbances at Lag 0

Study	Design & Methods	Concentrations[1]	Effect Estimates (95% CI)
			Heart failure at Lag 0, Lag 2, and Lags 0 -2 COPD at Lag 0, Lag 1, and Lags 0-2 and respiratory tract infections at Lag 2 and Lags 0-2. Fig 3: Point estimates and 95% posterior intervals of the % change in admission rates per 10 μg/m^3 (regional relative rates). Summary: For cardiovascular diseases, all estimates in the Midwestern, Northeastern, and Southern regions were positive, while estimates in the other regions (South, West, Central, Northwest) were close to 0. For respiratory disease, there were larger effects in the Central, Southeastern, Southern, and Western regions than in the other regions. Fig 4: Point estimates and 95% posterior intervals of the % change in admission per 10 μg/m^3 (Eastern vs.. Western regions): Summary: All estimates for cardiovascular outcomes were positive in the U.S. Eastern region but not in the U.S. Western region. The estimates for respiratory tract infections were larger in the Western region than in the Eastern region. The estimates for CCPD were positive in the both regions.

(2002, 035429) **Period of Study:**Apr 1996-Jun 1996 **Location:** Paris, France	**Outcome:** Incident and prevalent episodes of asthma attacks, nocturnal cough, wheeze, symptoms of irritation, respiratory infections, supplementary use of β2-agonists, Z-transformed peak expiratory flow (PEF), daily PEF variability **Age Groups:** 7-15 yr old **Study Design:** Cohort **N:** 82 children **Statistical Analyses:** Linear regression, logistic regression, GEE **Covariates:** Effects of time trend, day of the week, weather, pollen levels **Season:** Spring/summer **Lags Considered:** 0, 0-2 mean, 0-4 mean	**Pollutant:** PM_{10} **Averaging Time:** Daily **Mean (SD):** 23.5 (8.4) **Range (Min, Max):** 9.0, 44.0 **Monitoring Stations:** 5 **Copollutant (correlation):** BS: 0.59 SO_2: 0.70 NO_2: 0.54 O_3: 0.21 Temp: 0.04 Humid: -0.41	**PM Increment:** 10 μg/m^3 for binary responses data (results that use odds ratios [ORs]) **Incident episodes of** 1) Asthma a) lag 0: 1.06 (0.61, 1.83) b) 0-2 mean: 1.09 (0.48, 2.49) c) 0-4 mean: 1.07 (0.44, 2.65) 2) Nocturnal cough a) lag 0: 1.10 (0.88, 1.37) b) 0-2 mean: 1.03 (0.77, 1.37) c) 0-4 mean: 1.11 (0.86, 1.42) 3) Respiratory infections a) lag 0: 0.64 (0.35, 1.15) b) 0-2 mean: 0.74 (0.38, 1.43) c) 0-4 mean: 0.99 (0.58, 1.68) **Prevalent episodes of** 1) Asthma a) lag 0: 1.07 (0.72, 1.59) b) 0-2 mean: 1.18 (0.64, 2.17) c) 0-4 mean: 1.16 (0.63, 2.13) 2) Nocturnal cough a) lag 0: 1.05 (0.83, 1.34) b) 0-2 mean: 1.10 (0.81, 1.50) c) 0-4 mean: 1.09 (0.79, 1.52) 3) Respiratory infections a) lag 0: 1.17 (0.68, 2.03) b) 0-2 mean: 1.31 (0.51, 3.36) c) 0-4 mean: 1.71 (0.71, 4.12) 4) Eye irritation a) lag 0: 1.18 (1.01, 1.39) b) 0-2 mean: 1.28 (1.03, 1.59) c) 0-4 mean: 1.42 (1.12, 1.80) **Analysis restricted to days with no steroid use:** **Incident episodes of** 1) Eye irritation a) lag 0: 1.07 (0.66, 1.71) b) 0-2 mean: 0.83 (0.45, 1.53) c) 0-4 mean: 0.92 (0.46, 1.83) 2) Throat irritation a) lag 0: 1.33 (0.66, 2.69) b) 0-2 mean: 1.28 (0.58, 2.80) c) 0-4 mean: 1.06 (0.38, 2.95) 3) Nose irritation a) lag 0: 0.74 (0.48, 1.13) b) 0-2 mean: 0.76 (0.42, 1.36) c) 0-4 mean: 0.96 (0.53, 1.73) **Prevalent episodes of** 1) Eye irritation a) lag 0: 1.20 (0.88, 1.65) b) 0-2 mean: 1.71 (0.97, 3.01) c) 0-4 mean: 1.97 (1.03, 3.76) 2) Throat irritation a) lag 0: 1.23 (0.83, 1.82) b) 0-2 mean: 1.08 (0.68, 1.73) c) 0-4 mean: 0.91 (0.47, 1.73) 3) Nose irritation a) lag 0: 1.20 (0.91, 1.58) b) 0-2 mean: 1.09 (0.78, 1.52) c) 0-4 mean: 1.09 (0.73, 1.61) **Notes:** The authors noted that incident or prevalent wheeze was not correlated with levels of any type of pollutant. Also, they state no relationship was observed between PEF variables and levels of PM. The authors also note that in a multipollutant model assessing independent effects of PM and O_3 on prevalent episodes of eye irritation (mean 0-4), the PM parameter decreased and was not significant ($p = 0.19$).

(2007, 091064) **Period of Study:** 1996-1999 **Location:** Mexico City, Mexico	**Outcome:** Lung function: FEV_1, FVC, $FEF_{25-75\%}$ **Age Groups:** Children 8 yr old at time of cohort recruitment **Study Design:** School-based "dynamic" cohort study **N:** 3170 children 14,545 observations **Statistical Analyses:** Three-level generalized linear mixed models with unstructured variance-covariance matrix **Covariates:** Age, body mass index, height, height by age, weekday spent outdoors, environmental tobacco smoke, previous-day mean air pollutant concentration, time since first test **Dose-response Investigated?** No **Statistical Package:** SAS **Lags Considered:** 0-1 days	**Pollutant:** PM_{10} **Averaging Time:** 24 h, 6 mo **Mean (SD):** 24-h averaging Tlalnepantla: 66.7 (35.6) Xalostoc: 96.7 (49.4) Merced: 79.3 (40.8) Pedregal: 53.4 (31.9) Cerro de la Estrella: 69.6 (35.3) 6-mo averaging **Mean:** 75.6 **Percentiles:** 6-mo averaging 25th: 55.8 50th(Median): 67.5 75th: 92.2 **Monitoring Stations:** 5 sites for PM_{10}, 10 for other pollutants **Copollutant:** O_3 NO_2	**PM Increment:** IQR PM_{10}, 6-LC: 36.4 **GIRLS** **One-pollutant model** FVC: -39 [-47: -31] FEV: -29 [-36: -21] $FEF_{25-75\%}$: -17 [-36: 1] FEV_1/FVC: 0.12 [0.07: 0.17] **Two-pollutant model** PM_{10}, 6-LC & O_3 FVC: -30 [-39: -22] FEV: -24 [-31: -16] $FEF_{25-75\%}$: -9 [-26: 9] FEV_1/FVC: 0.10 [0.06: 0.15] PM_{10}, 6-LC & NO_2 FVC: -21 [-30: -13] FEV: -17 [-25: -8] $FEF_{25-75\%}$: -23 [-43: -4] FEV_1/FVC: 0.07 [0.02: 0.13] **Multipollutant model** PM_{10}, 6-LC, O_3, & NO_2 FVC: -14 [-23: -5] FEV: -11 [-20: -3] FEF25-75%: -7 [-27: 12] FEV_1/FVC: 0.08 [0.03: 0.13] **BOYS** **One-pollutant model** FVC: -33 [-41: -25] FEV: -27 [-34: -19] $FEF_{25-75\%}$: -18 [-34: -2] FEV_1/FVC: 0.04 [-0.01: 0.09] **Two-pollutant model** PM_{10}, 6-LC & O_3 FVC: -28 [-36: -19] FEV: -22 [-30: -15] $FEF_{25-75\%}$: -10 [-27: 7] FEV_1/FVC: 0.04 [-0.01: 0.09] PM_{10}, 6-LC & NO_2 FVC: -16 [-26: -7] FEV: -19 [-27: -10] $FEF_{25-75\%}$: -26 [-44: -9] FEV_1/FVC: 0.005 [-0.06: 0.05] **Multipollutant model** PM_{10}, 6-LC, O_3, & NO_2 FVC: -12 [-22: -3] FEV: -15 [-23: -6] $FEF_{25-75\%}$: -12 [-30: 6] FEV_1/FVC: -0.002 [-0.06: 0.05] Long-term exposure to O_3, PM_{10}, and NO_2 is associated with decrements in FVC and FEV_1 growth in Mexico City schoolchildren. In a multipollutant model, PM_{10} (-12%), O_3 (-9%), and NO_2 (-41%) each contribute independently and statistically significantly to diminished FVC growth. For FEV_1, however, the multipollutant model indicates that only PM_{10} (-15%) and NO_2 (-25%) each contribute independently and statistically significantly to diminished FEV_1 growth.

Study	Design & Methods	Concentrations[1]	Effect Estimates (95% CI)
Reference: Allen et al. (2008, 156208) **Period of Study:** 1999-2002 (additional PM composition data collected Dec 2000 and May 2001) **Location:** Seattle, USA	**Outcome:** Daily changes in exhaled nitric oxide (FENO) and 4 lung function measures, midexpiratory flow (MEF), peak expiratory flow (PEF), forced expiratory volume in 1 second (FEV_1), and forced vital capacity (FVC) **Age Groups:** 6-13 yr **Study Design:** Panel study **N:** 19 children with asthma **Statistical Analyses:** Linear mixed effects model with random intercept to test for within participant associations **Covariates:** Temperature, relative humidity, BMI, age, and, in the case of FENO, ambient NO measured at a centrally located monitoring site Models also included a term for within-participant, within-session effects, and a term for participant between-session effects **Effect modification**: Decided a priori to include interaction term for $PM_{2.5}$ exposure and inhaled corticosteroids	**Pollutant:** $PM_{2.5}$ **Mean (SD):** 11.23 (6.48) **Range (Min, Max):** 2.76-40.38 25th: 6.38 75th: 14.73 **Copollutant (correlation):** Ambient LAC* r=0.83 Ambient LG**r=0.84 Personal $PM_{2.5}$: r=0.34 Personal LAC: r=0.54 Ambient-generated $PM_{2.5}$: r=0.87 Nonambient-generated $PM_{2.5}$: r=-0.06 * LAC Light-absorbing carbon ** LG: Leroglucosan (a marker of wood smoke)	Health effect estimates presented in graphic form (Fig 1). Summary from text is as follows: Personal LAC, personal $PM_{2.5}$, and ambient-generated $PM_{2.5}$ were associated with ($p < 0.05$) and ambient $PM_{2.5}$ was marginally associated ($p=0.09$) with increased FENO. Neither of the ambient combustion markers (LAC, LG) nor nonambient-generated $PM_{2.5}$ was associated with FENO changes. All of the ambient concentrations were associated with decrements in PEF and MEF while ambient-generated $PM_{2.5}$ was marginally associated ($p < 0.10$). Only ambient LG was associated with a decrease in FEV_1 and there were no associations between exposure metrics and FVC.
