			road: 51.3 (-8.3, 110.8) **Exploratory/sensitivity analyses (also presented in figures):** **Detectable AAC RR (95%CI):** Among women: 1.14 (1.00, 1.30) Among persons >65yrs: 1.10 (1.01, 1.19) Among users of lipid-lowering medications: 1.14 (1.00, 1.30) Among Hispanics: 1.22 (1.03, 1.45) Imputing missing covariates among residentially stable participants: 1.08 (0.98, 1.19) **Agatston score % change (95%CI):** Among Hispanics: 64 (-4, 133) Among persons earning >$50,000: 72 (5, 139) **Agatston score including those with Agatston = 0** **% change (95%CI):** Fully adjusted model: 41 (-12, 93) Among persons >65yrs: 75 (8, 143) Among diabetics: 149 (29, 270) Among users of lipid-lowering medications: 121 (25, 217) Among Hispanics: 141 (45, 236) Imputing missing **Covariates:** 49 (1.3, 100.1)

Study	Design & Methods	Concentrations[1]	Effect Estimates (95% CI)
Reference: Auchincloss et al. (2008, 156234) **Period of Study:** Jul 2000-Aug 2002 **Location:** 6 U.S. communities (Baltimore City and Baltimore County, Maryland Chicago, Illinois Forsyth County, North Carolina Los Angeles, California Northern Manhattan and the Bronx, New York and St. Paul, Minnesota) part of MESA (Multi-ethnic Study of Atherosclerosis)	**Outcome (ICD9 and ICD10):** Blood pressure: systolic (SBP), diastolic (DBP), mean arterial (MAP), pulse pressure (PP) Avg of 2nd and 3rd BP measurement used for analyses **Age Groups:** 45-84 yr **Study Design:** Cross-sectional (Multi-Ethnic Study of Atherosclerosis baseline examination) **N:** 5,112 persons (free of clinically apparent cardiovascular disease) **Statistical Analyses:** Linear regression Secondary analyses used log binomial models to fit a binary hypertension outcome **Covariates:** Age, sex, race/ethnicity, per capita family income, education, BMI, diabetes status, cigarette smoking status, exposure to ETS, high alcohol use, physical activity, BP medication use, meteorology variables, and copollutants Examined site as a potential confounder and effect modifier Heterogeneity of effects also examined by traffic-related exposures, age, sex, type 2 diabetes, hypertensive status, cigarette use **Season:** Adjusted for temperature and barometric pressure to adjust for seasonality (because seasons vary by the study sites) Also performed sensitivity analyses adjusting for season to examine the potential for residual confounding not accounted for by weather variables **Dose-response Investigated?** Assessed nonlinear relationships-no evidence of strong threshold/nonlinear effects for $PM_{2.5}$ **Statistical Package:** NR	**Pollutant:** $PM_{2.5}$ **Averaging Time:** 5 exposure metrics constructed: prior day, avg of prior 2 days, prior 7 days, prior 30 days, and prior 60 days **Mean (SD):** Prior day: 17.0 (10.5) Prior 2 days: 16.8 (9.3) Prior 7 days: 17.0 (6.9) Prior 30 days: 16.8 (5.0) Prior 60 days: 16.7 (4.4) **Percentiles:** NR **Range (Min, Max):** NR **Monitoring Stations:** Used monitor nearest the participant's residence to calculate exposure metrics **Copollutant (correlation):** SO_2 NO_2 CO Traffic-related exposures (straight-line distance to a highway; total road length around a residence)	**PM Increment:** 10 $\mu g/m^3$ (approx. equivalent to difference between 90th and 10th percentile for prior 30 day mean) **Effect Estimate [Lower CI, Upper CI]:** Adjusted mean difference (95% CI) in PP and SBP (mmHg) per 10 $\mu g/m^3$ increase in $PM_{2.5}$ (avg for the prior 30 days) **Pulse Pressure** Adjustment variables: Person-level **Covariates:** 1.04 (0.25, 1.84) Person-level cov., weather: 1.12 (0.28, 1.97) Person-level cov., weather, gaseous copollutants: 2.66 (1.61, 3.71) Person-level cov., study site: 0.93 (-0.04, 1.90) Person-level cov., study site, weather: 1.11 (0.01, 2.22) Person-level cov., study site, weather, gaseous copollutants: 1.34 (0.10, 2.59) **Systolic Blood Pressure** Adjustment variables: Person-level **Covariates:** 0.66 (-0.41, 1.74) Person-level cov., weather: 0.99 (-0.15, 2.13) Person-level cov., weather, gaseous copollutants: 2.8 (1.38, 4.22) Person-level cov., study site: 0.86 (-0.45, 2.17) Person-level cov., study site, weather: 1.32 (-0.18, 2.82) Person-level cov., study site, weather, gaseous copollutants: 1.52 (-0.16, 3.21) **Additional results:** Associations became stronger with longer averaging periods up to 30 days. For example: Adjusted (personal covariates and weather) mean differences in PP: Prior day: -0.38 (-0.76, 0.00) Prior 2 days: -0.22 (-0.65, 0.21) Prior 7 days: 0.52 (-0.08, 1.11) Prior 30 days: 1.12 (0.28, 1.97) Prior 60 days: 1.08 (0.11, 2.05) (Pattern held for additional adjustments and for SBP results. Therefore, only results for 30-day mean differences were presented) **Additional results (not presented):** None of DBP results were statistically significant. Rresults for MAP were similar to SBP, though weaker and generally not significant Effect modification: associations between $PM_{2.5}$ and BP were stronger for persons taking medications, with hypertension, during warmer weather, in the presence of high NO_2, residing ≤ 300m from a highway, and surrounded by a high density of roads (Fig 1) Associations were not modified for age, sex, diabetes, cigarette smoking, study site, high levels of CO or SO_2, season , nor residence ≤ 400m fro a highway **Note:** supplementary material available on-line

Study	Design & Methods	Concentrations[1]	Effect Estimates (95% CI)
Reference: Bayer-Oglesby et al. (2005, 086245) **Period of Study:** 1992-2001 **Location:** Switzerland (Lugano, Zurich, Bern, Geneva, Anieres, Biel, Langnau, Payerne, & Montana)	**Outcome:** Respiratory symptoms (chronic cough, bronchitis, cold, dry cough, conjunctivitis, wheeze, sneezing, asthma, & hay fever) **Age Groups:** 6-15 yr **Study Design:** Cross-sectional **N:** 9,591 children **Statistical Analyses:** Logistic regression models **Covariates:** Age, sex, nationality, parental education, number of siblings, farming status, low birth weight, breast feeding, smoking, family history of asthma, bronchitis and/or atopy, mother who smokes, indoor humidity, mode of cooking & heating, carpeting, pets, removal of carpets/pets for health reasons, completed questionnaire & month, days max temperature <0°C, mother's belief of association between environmental exposures & respiratory health **Dose-response Investigated?** Yes **Statistical Package:** STATA	**Pollutant:** PM_{10} **Averaging Time:** 12-mo avg **Mean (SD):** NR **Range (Min, Max):** NR **Monitoring Stations**: 9 **Copollutant (correlation):** NR	**PM Increment:** 10 µg/m^3 "Fig 2 shows that declining levels of PM_{10} were associated with declining prevalence of chronic cough, bronchitis, common cold, nocturnal dry cough, and conjunctivitis symptoms. For wheezing, sneezing, asthma, and hay fever, no significant association could be seen with declining PM_{10} levels." "Fig 3 illustrates that, on an aggregate level, across regions the mean change in PM_{10} levels (r pearson = 0.81, p = 0.008). The strongest decline of adjusted prevalence of nocturnal dry cough was observed in Geneva, Lugano, and Anieres, where the strongest reduction of PM_{10} had also been achieved."
Reference: Burr et al. (2004, 087809) **Period of Study:** 3 wk in Jul and Jan 1997 and 2 wk in Nov 1996 and Apr 1997 **Location:** North Wales, England	**Outcome:** Self-report of symptoms only for wheeze, cough, phlegm, rhinitis, and itchy eyes. **Age Groups:** all **Study Design:** Repeated measures **N:** 386 persons in congested streets and 425 in the uncongested streets in 1996/1997. Of these, 165 and 283 completed the second phase of the study.	**Pollutant:** PM_{10} **Averaging Time:** Mean hourly concentrations **Mean (SD):** SD NR Congested streets - 1996-97 35.2 1998-99 27.2 Uncongested Streets 1996-97 11.6 1998-99 8.2 **Monitoring Stations**: 1 in congested street and 1 in uncongested	**Percent change PM10 in congested streets: 22.7** **Percent change PM10 in uncongested streets: 28.9** Uncongested street sampling site was 20 m from the congested street sampler. The opening of the by-pass produced a reduction in pollution in the congested streets. The health effects of these changed is likely to be greater for nasal and ocular symptoms than for lower respiratory symptoms. Uncertainty about the causality arises from low response rates and conflicting trends in respiratory and nasal symptoms.

Reference: Cavanagh et al. (2007, 189802) **Period of Study:** Mar-Aug 2004 **Location:** Christchurch, New Zealand	**Outcome:** A clinical study of excretion of 1-hydroypyrene (1-OHP) as a marker of PAH exposure **Age Groups:** Non-smoking males aged 12-18 yr **Study Design:** Comparison of 2 high pollution events and 2 low pollution events **N:** 89 male students in a boarding school **Statistical Analyses:** Wilcoxon signed rank test for paired observations, Mann-Whitney U test **Season:** Winter **Dose-response Investigated?** No	**Pollutant:** PM_{10} **Averaging Time:** 24 h **Mean (SD):** Fall Low Outdoor 19 Indoor NA Winter I Outdoor 43 Indoor 38 Winter II Outdoor 72 Indoor 84 Winter Low Outdoor 12 Indoor 16 **Monitoring Stations**: One inside the boarding house, and one outside	Urinary 1-OHP were raised after high-pollutions events. Peaks were slightly higher than for U.S. non-smokers of similar ages and slightly lower than for German non-smokers of similar ages. Urinary 1-OHP was slightly higher in asthmatics compared to non-asthmatics. There were no indoor sources of PAHs (wood-burning stoves, tobacco smoke). Diet is another source of PAHs, but all students ate in the boarding house. These results suggest 1-OHP could be used as a biomarker of ambient air pollution.

Reference: Janssen et al. (2003, 133555) **Period of Study:** Apr 1997-Jul 1998 **Location:** Netherlands-24 schools	**Outcome:** Symptoms of asthma and allergic disease (asthma, conjunctivitis, hay fever, itchy rash, eczema, phlegm, bronchitis), skin prick test (SPT) reaction to allergens, lung function (forced vital capacity [FVC], forced expiratory volume in 1 second [FEV_1], and positive test for fall in $FEV_1 \geq 15\%$ after inhalation of maximal 23 mL hypertonic saline [BHR = bronchial hyper-responsiveness]) **Age Groups**: 7-12 yr old **Study Design:** Cohort **N:** 24 schools (see notes) **Statistical Analyses:** Multilevel model **Covariates:** Age, sex, non-Dutch nationality, cooking on gas, current parental smoking, current pet possession, parental education level, number of persons in the household, presence of an unvented water heater in kitchen, questionnaire not filled out by the mother, presence of mold stains in kitchen or living room or bedroom, parental respiratory symptoms, distance of home to motorway, cough or cold at time of lung function measurement, bronchitis or severe cold or flu in 3 wk preceding measurement, season **Dose-response Investigated?** No **Statistical Package**: MLwiN	**Pollutant:** $PM_{2.5}$ **Averaging Time:** Annual **Mean (SD):** 20.5 µg/m^3 (2.2) **Percentiles:** 25th: 18.6 50th (Median): 20.4 75th: 22.1 **Range (Min, Max):** 17.3, 24.4	**PM Increment:** 'Difference between the maximum and the minimum of the exposure indicator' (3.5 µg/m^3) **RR Estimate [Lower CI, Upper CI] lag:** Current wheeze 1.51 (0.90, 2.53) Asthma ever 1.03 (0.59, 1.82) Current conjunctivitis 2.08 (1.17, 3.71) Hay fever ever 2.28 (1.13, 4.57) Current itchy rash 1.63 (0.91, 2.89) Eczema ever 1.31 (0.94, 1.83) Current phlegm 1.53 (0.74, 3.19) Current bronchitis 1.71 (0.84, 3.50) Elevated total IgE 1.45 (0.74, 2.84) Any allergen (spt reactivity) 1.33 (0.83, 2.11) Indoor allergens (spt reactivity) 1.17 (0.70, 1.94) Outdoor allergens (spt reactivity) 1.90 (1.06, 3.40) FVC < 85% predicted 0.54 (0.29, 1.00) FEV_1 < 85% predicted 0.88 (0.37, 2.09) BHR 0.93 (0.51, 1.68) **Notes:** Fig 1 of the article illustrates the association between exposures, including $PM_{2.5}$, and various respiratory symptoms among children with and without a positive SPT and positive BHR. In general, the association between $PM_{2.5}$ and respiratory symptoms were higher for children with a positive SPT or BHR, except for the outcome of current phlegm. This effect appeared to be the strongest for children with a positive BHR, particularly for current wheeze and current bronchitis. The authors also reported separate analyses for children with SPT reactivity for indoor and outdoor allergens, but did not report any clear differences between the two groups. The authors did report, in the text, that the OR of $PM_{2.5}$ exposure for children sensitized for outdoor allergens was 7.64 for current itchy rash ($p < 0.05$).

Reference: Burr et al. (2004, 087809) **Period of Study:** 3 wk in Jul and Jan 1997 and 2 wk in Nov 1996 and Apr 1997 **Location:** North Wales, England	**Outcome:** Self-report of symptoms only for wheeze, cough, phlegm, rhinitis, and itchy eyes. **Age Groups:** All **Study Design:** Repeated measures **N:** 386 persons in congested streets and 425 in the uncongested streets in 1996/1997. Of these, 165 and 283 completed the second phase of the study.	**Pollutant:** $PM_{2.5}$ **Averaging Time:** Mean hourly concentrations **Mean (SD):** Congested Streets 1996-97 21.2 1998-99 16.2 Uncongested Streets 1996-97 6.7 1998-99 4.9 **Monitoring Stations**: 1 in congested street and 1 in uncongested	% change PM_{10} in congested streets: 23.6 % change PM_{10} in uncongested streets: 26.6 Uncongested street sampling site was 20 m from the congested street sampler. The opening of the by-pass produced a reduction in pollution in the congested streets. The health effects of these changed are likely to be greater for nasal and ocular symptoms than for lower respiratory symptoms. Uncertainty about the causality arises from low response rates and conflicting trends in respiratory and nasal symptoms.

Reference: McConnell, et al. (2006, 180226) **Period of Study:** 1996-1999 **Location:** 12 Southern California communities	**Outcome:** Prevalence of bronchitic symptoms (yrly). **Age Groups:** 10-15-yr-old **Study Design:** Longitudinal cohort **N:** 475 asthmatic children **Statistical Analyses:** Multilevel logistic mixed effects models. **Covariates:** Age, second-hand smoke Personal smoking history Sex, race. **Dose-response Investigated?** No **Statistical Package:** SAS	**Pollutant:** $PM_{2.5}$ **Averaging Time:** 365 days **Percentiles:** Community by yr (n = 48 = 12 communities · 4 yr) 25th: NR 50th(Median): 3.4 75th: NR **Range (Min, Max):** Community by yr (n = 48 = 12 communities · 4 yr): (0.89, 8.7) **Monitoring Stations**: 12 **Copollutant:** O_3 NO_2 EC OC Acid vapor (acetic and formic acid)	**PM Increment:** 3.4 µg/m^3 **OR Estimate [Lower CI, Upper CI]** $PM_{2.5}$ Dog (n = 292): 1.56 [1.15: 2.12] No dog (n = 183): 1.03 [0.71: 1.49] $PM_{2.5}$*Dog interaction p-value: 0.06 Cat (n = 202): 1.30 [0.90: 1.88] No Cat (n = 273): 1.36 [0.99: 1.83] $PM_{2.5}$*Cat interaction p-value: 0.87 Neither pet (n = 112): 1.11 [0.71: 1.74] Cat only (n = 71): 0.85 [0.46: 1.57] Dog only (n = 161): 1.53 [1.04: 2.25] Both pets (n = 131): 1.58 [1.02: 2.46] Results suggest that dog ownership, a source of residential exposure to endotoxin, may worsen the severity of respiratory symptoms from exposure to air pollutants in asthmatic children. Although $PM_{2.5}$ was associated at a statistically significant level with ownership of both cats and dogs, it appears that dog ownership (with or without a cat) specifically worsens the association between $PM_{2.5}$ and respiratory symptoms in asthmatic children.

Annex F. Source Apportionment Studies

Table F-1. Epidemiologic studies of ambient PM sources, factors, or constituents

Reference: Andersen et al. (2007, 093201) **Location:** 1 monitor in Copenhagen, Denmark/ 6 yr, but apportionment done for 1.5 yr only (2002-2003) **Particle Size:** PM_{10}	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 31	**Grouping method:** PCA + PMF/CMB hybrid (COPREM) **# of groups:** 12, but only 6 used in relating to health effects, and CO, NO_2	**Groups/Factors/ Sources:** Road, vehicle, salt, biomass, oil, coal, rock, lime, $NaNO_3$, NH_4NO_3, $(NH_4)_2SO_3$, (NH_4SO_4)	**PM variables used:** Mass contribution of sources
	Results: Single pollutant models: Biomass, secondary compounds, oil, and crustal significantly associated with CVD HA (4-day ma). Biomass and secondary components significantly associated with respiratory HA (5-day ma). No significant effects for asthma HA in children (6-day ma). **Two pollutant models:** Crustal effect for CVD admissions remained robust. Biomass effect for respiratory admissions was highest. Effect of vehicle source remained robust for asthma admissions in children in presence of other PM_{10} sources.					
Reference: Bell et al. (Bell et al., 2009, 191007) **Location:** $PM_{2.5}$: 2000-2005 (6 yr)/106 US counties/EPA composition data PM_{10}: 1987-2000/100 counties/EPA composition data **Particle Size:** PM_{10}, $PM_{2.5}$	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 16 elements + NO_3, SO_4, EC, OC	**Grouping method:** NR **# of groups:** NR	**Groups/Factors/ Sources:** NR	**PM variables used:** Every component (16 elements + NO_3, SO_4,EC, OC)
	Results: Mortality: Ni significantly increased PM_{10} mortality risks. However, effect of Ni was not significant when New York City was removed, in a sensitivity analysis conducted by selectively removing cities from the overall estimate. **Hospital Admissions:** CVD and respiratory HAs higher in counties with higher EC, Ni, and V $PM_{2.5}$. In CVD association between $PM_{2.5}$, RR and V robust to inclusion of EC or V, and V robust to inclusion of EC.					
Reference: Cakmak et al. (2009, 191995) **Location:** 1 monitor in Santiago, Chile **Particle Size:** $PM_{2.5}$	**Subjects:** NR **Exposure:** 1998-2009 (8.3 yr)	**N:** NR	**Number of Constituents considered for grouping:** 16 elements + CO, NO_2, SO_2, EC, OC	**Grouping method:** PCA **# of groups:** 4	**Groups/Factors/ Sources:** Vehicle (CO, NO_2, EC, OC), Soil (Al, Ca, Fe, Si), Combustion (Cr, Cu, Fe, Mn, Zn), Factor 4 (Br, Cl, Pb)	**PM variables used:** individual components, then groupings
	Results: Individual components: EC, OC only stat. sign. risk estimates for total, cardiac, and respiratory mortality for 1-day lag after adjustment for other elements. **Groupings:** Lag 1. Vehicle factor: Increased total mortality, cardiac mortality, and respiratory mortality. Soil factor: increased cardiac mortality and respiratory mortality (but smaller than vehicle factor RRs). Combustion factor: greatest RR for respiratory mortality, but significant for total and cardiac mortality. Factor 4: increased total, cardiac, and respiratory mortality. Point estimates for Factor 1 significantly different from Factors 3 and 4. Elderly had higher risk estimates for combustion and soil sources. No significant effect modification by gender or season.					
Reference: Franklin et al. (2008, 097426) **Location:** STN/25 communities/2000-2005 (6 yr) **Particle Size:** $PM_{2.5}$	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 15 elements + EC, OC, NO_3	**Grouping method:** NR **# of groups:** NR	**Groups/Factors/ Sources:** NR	**PM variables used:** Every component
	Results: The $PM_{2.5}$-mortality association was significantly modified by Al, As, Sulfate, Ni, and Si. When including a combination of species proportions and using backwards elimination Al, sulfate, and Ni remained significant. Al and Ni explained most of the residual heterogeneity.					

Note: Hyperlinks to the reference citations throughout this document will take you to the NCEA HERO database (Health and Environmental Research Online) at http://epa.gov/hero. HERO is a database of scientific literature used by U.S. EPA in the process of developing science assessments such as the Integrated Science Assessments (ISA) and the Integrated Risk Information System (IRIS).

Reference: Gent et al. (2009, 180399) **Location:** 2 monitors in New Haven, CT/ 3.5 yr **Particle Size:** $PM_{2.5}$	**Subjects:** Children with physician diagnosed asthma and symptoms or medication use in previous 12 mo, and resided within 30km of New Haven county monitor **Exposure:** NR	**N:** 149 children	**Number of Constituents considered for grouping:** 17 elements + EC	**Grouping method:** PCA **# of groups:** 6	**Groups/Factors/ Sources:** Vehicle (EC, Zn, Pb, Cu, Se), road dust (Si, Fe, Al, Ca, Ba, Ti), sulfur (S, P), biomass burning, (K) oil (V, Ni), sea salt (Na, Cl) In addition, effects of NO_2, CO, SO_2, and O_3 were included in the health outcomes model	**PM variables used:** Groupings and individual elements
	Results: Overall: Trace elements originating from motor vehicle, road dust, biomass burning, and oil sources associated with symptoms and/or medication use. No associations with S or sea salt. **Specific Results:** $PM_{2.5}$ mass from motor vehicle or road dust associated with increased odds of respiratory symptoms or inhaler use. Reduced odds of wheeze or inhaler use with same day S. Significant reductions odds of wheeze with biomass burning. **Co-pollutant:** Positive effects of motor vehicles and road dust on wheeze were robust to the inclusion of gaseous copollutants. However, NO_2 increases association with wheeze.					
Reference: Ito et al. (2006, 088391) **Location:** Washington, DC **Particle Size:** $PM_{2.5}$	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** NR	**Grouping method:** Comparison of: PMF; (absolute) PCA; UNMIX **# of groups:** 6-10 **Groups/ Factors/ Sources:** Different research groups gave different names to sources	**Sources for which association with health was analyzed:** Soil, traffic, Secondary SO_4, NO_3 (Washington, DC only), residual oil (Washington, DC only), Wood smoke/ biomass combustion, Sea salt, incinerator (Washington, DC only), primary coal (Washington, DC only), Cu smelter (Phoenix only)	**PM variables used:** Mass contribution of sources
	Results: Overall, $PM_{2.5}$ effects observed at lag 3. Lag structure of association varied across source types, but consistent across investigators for total (nonaccidental mortality): soil factor - mostly positive at various lags (not significant); secondary sulfate - strongest association at lag 3; nitrate - mostly negative except at lag 3; residual oil - strongest association at lag 2 (not significant); wood-burning - increasing association as lag increases (not significant); incinerator - significant negative associations at lag 0; primary coal - significant association at lag 3.					
Reference: Laden et al. (2000, 012102) **Location:** Monitors in 6 Eastern US cities (Harvard Six Cities Study) **Particle Size:** NR	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 15 elements	**Grouping method:** PCA **# of groups:** 8	**Groups/ Factors/ Sources:** Soil/crustal (PM fine), mobile vehicle exhaust (PM fine), coal (PM fine), fuel oil; metals, salt manganese, residual	**PM variables used:** Tracers: Si, V, Cl, Pb, Se
	Results: Lag 0-1 avg for all results. Overall 6 cities, mobile source factor (using Pb as tracer) had greatest association with daily mortality (3.4%) with 10 µg/m3 increase. The greatest effects for mortality due to mobile sources were observed in Madison (Portage), Knoxville (Kingston-Harriman), and St. Louis, although the Madison results were not statistically significant. The coal source factor was only significant in Boston (Watertown) - 2.8% increase in mortality and the overall percent increase was also significant (1.1%). Deaths from pneumonia attributable to coal combustion sources was 7.9% (CI 3.1-12.7%) and statistically significant. The crustal factor was not associated with mortality in any city, although this factor was not a significant predictor in the regression model for Boston (Watertown) due to its low contribution to $PM_{2.5}$ mass. For specific elements included simultaneously, S, Pb, and Ni were significantly associated with overall mortality (3.0, 1.6, 1.5%, respectively). Boston had the greatest percent increase in mortality for S (7.9%), Knoxville for Pb (15.0%), and Steubenville for Ni (8.2%), although the CIs are all quite large. **Reanalysis results: (Schwartz, 2003, 042811)** Effects changed slightly. New percent increases in mortality for combined cities are 3.5 and 0.79 for traffic and coal, respectively. The coal factor in Boston decreased to 2.1% increased mortality. A residual oil factor in Boston and Steubenville resulted in at 22.9% increase in daily deaths (but was not significant in the original analysis).					
Reference: Lanki et al. (2006, 088412) **Location:** Monitors in Helsinki, Finland, Amsterdam,The Netherlands and Erfurt, Germany **Particle Size:** UF/$PM_{2.5}$	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 13 elements	**Grouping method:** Absolute PCA **# of groups:** 5	**Groups/ Factors/ Sources:** Crustal; long range transported; oil combustion; soil; traffic	**PM variables used:** Tracers: Si (crustal); S (long-range transport); Ni (oil combustion); Cl (salt); ABS (local traffic).
	Results: Highest observed effects were for crustal sources and salt at lag 3 (when analyzing sources), but not consistent or significant. In multipollutant models only ABS associated with ST-segment depression, but wide CIs. When examining indicator elements of a source, local traffic found to be the most toxic, but when examined per IQR long-range transport and traffic had similar effects.					

	Results: All had significant associations with mortality. Traffic density and EC had the largest effects.					
Reference: Lippmann et al. (2006, 091165) **Location:** U.S. **Particle Size:** PM_{10} for risk estimates, $PM_{2.5}$ for speciation data	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** NR	**Grouping method:** No grouping was performed # **of groups:** NR	**Groups/ Factors/ Sources:** NR	**PM variables used:** Mass contribution of 16 constituents
	Results: The strongest predictions of the variation in PM_{10} risk estimates across the 90 NMMAPs MSAs was for Ni and V. Elevated, but nonsignificant increases were associated with EC, Zn, $SO_4$2-, Cu, Pb, and OC. Al and Si had the lowest values.					
Reference: Mar et al. (2000, 001760) **Location:** 1 monitor in Phoenix, AZ **Particle Size:** NR	**Subjects:** Elderly only **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 10 elements, OC, EC, CO, NO_2; SO_2	**Grouping method:** Unspecified type of factor analysis # **of groups:** 3 or 5	**Groups/ Factors/ Sources:** Motor exhaust/road dust, soil, vegetative burning, local SO_2, regional SO_4	**PM variables used:** First used individual constituents: S, Zn, Pb, K, OC, EC, TC (AL+Si+Ca+Fe+Ti), then factor scores
	Results: Cardiovascular mortality associated with $PM_{2.5}$ mass on lag 1 and 4 (6 and 4%, respectively). EC and TC associated with CV mortality for lag 1 (RR = 1.05); OC was weakly associated with CV mortality for lags 1 and 3. For total mortality, regional sulfate was positively associated at lag 0, but negatively associated at lag 3. The local SO_2 and the soil factors were negatively associated with total mortality. For CV mortality, secondary sulfate was positively associated at lag 0, motor vehicle at lag 1, and vegetative burning at lag 3. **Reanalysis results** (Mar, 2003): Similar associations were observed.					
Reference: Mar et al. (2006, 086143) **Location:** Phoenix, AZ **Particle Size:** $PM_{2.5}$	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** NR	**Grouping method:** Comparison of: PMF (absolute); PCA; UNMIX # **of groups:** 6-10 **Groups/ Factors/ Sources:** Different labs gave different names to sources (see Hopke et al, table 2)	Sources for which association with health was analyzed: Soil, Traffic, secondary SO_4, NO_3, (Washington, DC only), residual oil (Washington, DC only), woodsmoke/ biomass combustion, sea salt, incinerator (Washington, DC only); primary coal (Washington, DC only); Cu smelter (Phoenix only)	**PM variables used:** Mass contribution of sources
	Results: Using daily $PM_{2.5}$ data found the following associations with cardiovascular mortality: Secondary sulfate - greatest effect observed for all sources and at lag 0; traffic - associated at lag 1; copper smelter associated at lag 0; sea salt - had the greatest statistical significance and observed at lag 5; biomass/wood burning - less consistent lag structure but greatest association at lag 3; soil - did not show an association or consistent lag structure. For total (nonaccidental) mortality associations were weaker and consistently observed for only: copper smelter - lag 0; sea salt - lag 5.					
Reference: Ostro et al. (2007, 091354) **Location:** Monitors in 6 CA counties, some with 2 monitors, for 4 yr **Particle Size:** $PM_{2.5}$	Subjects NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 15 elements, EC, OC; NO_3; SO_4, $PM_{2.5}$ mass	**Grouping method:** No grouping was performed # **of groups:** NA	**Groups/ Factors/ Sources:** NR	**PM variables used:** Mass contribution of every constituent
	Results: Effects were greater during the winter months. In the all year analysis, at 3-day lag associations observed for EC, OC, NO_3 and Zn. During winter months (Oct -March) effects observed for most species for both all-cause and cardiovascular mortality at lag 3 (EC, OC, SO_4, Ca, Fe, K, Mn, Pb, S, Si, Ti, Zn) and (OC, NO_3, SO_4, Fe, Mn, S, V, Zn), respectively.					
Reference: Ostro et al. 	Results: The following associations were observed with cardiovascular mortality: $PM_{2.5}$ (lag 3); EC (lag 2); NO_3 (lag 3); SO_4 (lag 3); Fe (lag 2); K (lag 2); S (lag 3); Ti (lag 2); Zn (lag 3).					

Reference: Peng et al. (2009, 191998) **Location:** 119 urban communities STN data/2000-2006 **Particle Size:** $PM_{2.5}$	**Subjects:** Medicare enrollees 65 or older **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** SO_4, NO_3, Si, EC, OCM, Na, NH_4	**Grouping method:** NR # **of groups:** NR	**Groups/Factors/ Sources:** Only suggested in discussion	**PM variables used:** Tracers
	Results: CVD HAs: EC associated with same-day CVD HAs in single and multi-pollutant models. In single pollutant models associations also observed for sulfate, nitrate, OCM, and ammonium. However, the sulfate, nitrate, OCM, and ammonium associations were reduced in the multi-pollutant models. **Respiratory HAs:** OCM associated with same-day respiratory HAs in single and multi-pollutant models. Some evidence for sulfate associations at one and two-day lag.					
Reference: Penttinen et al. (2006, 087988) **Location:** Helsinki 1996-1997 (7 mo) **Particle Size:** $PM_{2.5}$	**Subjects:** Adult asthma subjects, max 2 km from single monitor **Exposure:** NR	**N:** 78	**Number of Constituents considered for grouping:** Unknown	**Grouping method:** PCA # **of groups:** 6	**Groups/Factors/ Sources:** Long range (PM mass, S, K, Zn), local combustion-traffic (Cu, Zn, Mn, Fe), soil (Si, Al, Ca, Fe, Mn), oil (V, Ni), salt (Na, Cl), unidentified	**PM variables used:** every component individually, then groupings
	Results: Long range $PM_{2.5}$ associated with decreased mean PEF in the morning at lag 1. Local combustion $PM_{2.5}$ associated with decreased mean PEF in the evening for lag 1. Local combustion $PM_{2.5}$ associated with decreased mean PEF in the afternoon and evening for 5-day mean lag. Negative significant association between long-range $PM_{2.5}$ and asthma symptom prevalence at lag 3. Sea-salt $PM_{2.5}$ negatively associated with bronchodilator use at lag 3 and 5-day mean lag. Sea-salt $PM_{2.5}$ negatively associated with corticosteroid use for 5-day mean lag. Unidentified $PM_{2.5}$ negatively associated with corticosteroid use at lag 1. Most consistent negative responses for local combustion, although not always significant. No consistent or significant associations between 5-day avg concentrations of elements and PEF, cough, asthma symptoms, or medication use.					
Reference: Riediker et al. (2004, 091261) **Location:** Inside 9 state police patrol cars **Particle Size:** $PM_{2.5}$	**Subjects:** Healthy male young police officers **Exposure:** 4 consecutive days	**N:** 9	**Number of Constituents considered for grouping:** 10 elements; 3 gaseous pollutants; 2 physical variables	**Grouping method:** PCA # **of groups:** 4 when 13+2 constituents included; 3 when only 9 "PM-associated" constituents included	**Groups/ Factors/ Sources:** Soil; automotive steel wear; gasoline combustion; speed-changing traffic	**PM variables used:** Mass contribution or score of sources
	Results: Using two different factor analysis models found most significant effects (MCL, SDNN, PNN_{50}, supraventricular ectopic beats, % neutrophils, % lymphocytes, MCV, von Willebrand Factor, and protein C) were for "speed-change factor" (i.e., Cu, S, aldehydes). Some associations observed for "crustal" and none for "steel wear" and "gasoline."					
Reference: Sarnat et al. (2008, 097972) **Location:** 1monitor in Atlanta. GA for 2 yr **Particle Size:** $PM_{2.5}$	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** NR	**Grouping method:** Comparison of: PMF, CMB-LGO, "a priori decision" # **of groups:** 9,11 (6 of them common between methods)	**Groups/ Factors/ Sources:** gasoline, diesel, wood smoke/ biomass burning, soil, secondary SO_4/ammonium sulfate, secondary nitrate/ ammonium nitrate, metal processing, railroad, bus and highway, cement kiln, power plants, other OC, ammonium bisulfate	**PM variables used:** Mass contribution or score of sources, and tracers
	Results: Sulfate secondary associated with 1.2-2.0% increase in RD visits, significant negative association RD visits and primary emissions from coal-fired power plants. CVD significantly associated with other OC (1.014), biomass (1.033), diesel and gas for CMB-LGO. For PMF and CVD visits: diesel (1.025), gas, wood smoke, metal processing (1.013). Year-long associations: PMF diesel, EC, CMB-LGO gas, Zn and biomass combustion sources (CMB-LGO biomass burning, PMF wood smoke, and K). Diesel and gas sources association with RD in the warm season (1.2-2.1% per IQR).					
Reference: Schreuder et al. (2006, 097959) **Location:** 1monitor in Spokane, WA for 7 yr **Particle Size:** $PM_{2.5}$	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 11 elements, TC, NO_3	**Grouping method:** Comparison of: PMF, UNMIX, Multilinear Engine # **of groups:** 8	**Groups/ Factors/ Sources:** Vegetative burning; As-rich Vehicle; SO_4; NO_3; Soil; Cu-rich; Marine	**PM variables used:** Tracers: TC (vegetative burning); As (As-rich); Zn (vehicle); Si (soil)
	Results: Si, As, and Zn were not associated with any health outcomes; while an IQR increase in TC (vegetative burning) was associated with a 2% increase in respiratory ED visits.					

Reference: Tsai et al. (2000, 006251) **Location:** 3 NJ sites for 2 summers (ATEOS study) **Particle Size:** NR	**Subjects:** NR **Exposure:** NR	**N:** NR	**Number of Constituents considered for grouping:** 8 metals, IPM, FPM, SO_4, CX, DCM, ACE, CO	**Grouping method:** Unspecified type of factor analysis # **of groups:** 5	**Groups/ Factors/ Sources:** Oil burning, motor emissions, resuspended dust, secondary aerosol, industrial sources	**PM variables used:** individual constituents, then factor scores, then tracers
	Results: RR associated with 10 µg/m3 increases: Newark - 1.03 for industrial and total daily deaths; 1.02 for sulfate and total daily deaths; 1.04 for sulfate and cardiopulmonary deaths. Camden - 1.11 for oil burning sources and total daily deaths; 1.10 industrial and total daily deaths; 1.12 for oil burning sources and cardiopulmonary daily deaths; 1.02 for sulfate and cardiopulmonary daily deaths					
Reference: Yue et al. (2007, 097968) **Location:** 1monitor in German city, 30.000 samples **Particle Size:** UF/$PM_{2.5}$	**Subjects:** Adult males **Exposure:** CAD	**n:** 56, data collected 12 times over 6 mo for every subject, but extended period of missing PM data	**Number of Constituents considered for grouping:** Apportionment based on particle size distribution.	**Grouping method:** PMF # **of groups:** 5	**Groups/ Factors/ Sources:** Airborne soil, local traffic, local fuel combustion, remote traffic (diesel), secondary aerosols	**PM variables used:** Mass contribution or score of sources
	Results: Overall, repolarization parameters influenced by traffic-related particles; vWF increased in response to traffic-related particles and combustion-generated aerosols. All source factors contributed to increasing CRP levels.					

Table F-2. Human clinical studies of ambient PM sources, factors, or constituents

Study: Gong et al. (2003, 042106) **Location:** Los Angeles, CA **Particle Size:** $PM_{2.5}$	**Subjects:** Adult 18-45, healthy vs. asthmatic **Exposure:** CAPs, healthy and asthmatic subjects exposed at different times	**N:** 12 healthy, 12 asthmatic	**Constituents considered for grouping:** 7 elements, EC, NO_3, SO_4	**Grouping method:** PCA # **of groups:** 4 (note: OC data was unavailable)	**Groups/ Factors/ Sources:** Crustal (Al Si CA K Fe),S (2 metrics of SO_4 + elemental S), Total Mass+NO_3, EC	**PM variables used:** Total mass, then tracers: SO_4, EC, Fe
	Results: Fe and EC associated with a decrease in ST-segment voltage 2 days post-exposure. EC associated with an increase in ST-segment voltage immediately following exposure. Sulfate content associated with a decrease in systolic BP 4 h post-exposure.					
Study: Gong et al. (2005, 087921) **Location:** Los Angeles, CA **Particle Size:** $PM_{2.5}$	**Subjects:** Elderly, COPD vs. healthy/ CAPs **Exposure:** NO_2 (full factorial)	**N:** 6 healthy, 18 COPD	**Constituents considered for grouping:** 7 elements + EC	**Grouping method:** PCA # **of groups:** 3 (note: OC was unavailable)	**Groups/ Factors/ Sources:** Crustal (Al Si CA K Fe), S (= SO_4),Na	**PM variables used:** Total mass, then tracers:, SO_4, Si, Fe, EC
	Results: Mass concentration of CAPs not observed to significantly affect lung function. However, sulfate content was associated with a decrease lung function (FEV_1 and FVC), which was enhanced by coexposure to NO_2.					
Reference: Huang et al. (2003, 087377) **Location:** Chapel Hill, NC **Particle Size:** $PM_{2.5}$	**Subjects:** Healthy adults **Exposure:** CAPs	**N:** 35 male; 2 female	**Constituents considered for grouping:** 8 elements and SO_4	**Grouping method:** PCA # **of groups:** 2	**Groups/ Factors/ Sources:** Fe/SO_4/Se/V/Zn/Cu	**PM variables used:** Factor scores, then mass contribution of all 9 constituents
	Results: Associations observed between sulfate,Zn, and Se content and increases in BAL neutrophils. Increases in fibrinogen associated with Cu, Zn, and V content.					
Reference: Urch et al. (2004, 055629) **Location:** Toronto, Canada **Particle Size:** $PM_{2.5}$	**Subjects:** Healthy adults 19-50 yr/CAPs **Exposure:** O_3	**N:** 23	**Constituents considered for grouping:** unknown	**Grouping method:** No grouping was performed # **of groups:** NA	**Groups/ Factors/ Sources:** NR	**PM variables used:** Every constituent in univariate analysis, then OC and SO_4 in multivariate analysis
	Results: CAPs-induced increase in diastolic BP significantly associated with carbon content of the particles.					
Reference: Urch et al. (2004, 055629) **Location:** Toronto, Canada **Particle Size:** $PM_{2.5}$	**Subjects:** Healthy adults/CAPs **Exposure:** O_3	**N:** 24	**Constituents considered for grouping:** 14 elements, EC, OC	**Grouping method:** No grouping was performed # **of groups:** NA	**Groups/ Factors/ Sources:** NR	**PM variables used:** Every constituent in univariate analysis, then OC and SO_4 in multivariate analysis
	Results: Both organic and EC content of CAPs associated with an increase in brachial artery vasoconstriction.					

Table F-3. Toxicological studies of ambient PM sources, factors, or constituents

Reference: Batalha et al. (2002, 088109) **Location:** Boston, MA **Particle Size:** $PM_{2.5}$	**Subjects:** Rats **Exposure:** CAPs (3-day mean CAPs concentration range: 126.1-481.0 µg/m3) CAPs (3-day mean CAPs concentration range: 126.1-481.0 µg/m3)	**N:** 7-10 rats × 2 levels CAPs × 2 levels SO_2 × 6 runs in different seasons	**Constituents considered for grouping:** 20 elements; OC; EC	**Grouping method:** Previous study in same city (Clarke et al., 2000, 013252) and PCA of this experiment's data # **of groups:** 4	**Groups/ Factors/ Sources:** V/Ni, S, Al/Si, Br/Pb	**PM variables used:** 4 tracers (Si, SO_4, V, Pb) and EC, OC in univariate step. 4 tracers (Si, SO_4, V, Pb) in multivariate step
	Results: Univariate analyses for first day not significant for L/W ratio. Univariate analyses for second and third day and second+third day mean were similar. Presented second+third day mean regression data. CAPs mass, Si, Pb, SO_4, EC, OC significant for decreased L/W ratio in normal+CB rats exposed to CAPs. Si, SO_4 significant for decreased L/W ratio in normal rats. Si, OC significant for decreased L/W ratio in CB rats. Multivariate analysis using normal+CB rats for Si, SO_4, V, Pb - only Si remained significant with decreased L/W ratio.					
Reference: Becker et al. (2005, 088590) **Location:** Chapel Hill, NC; repeated sampling for 1 yr **Particle Size:** PM_{10}	**Subjects:** Normal human bronchial epithelial and human AM **Exposure:** (2-3X105 cells/mL; 11 or 50 µg/mL)	**N:** NR	**Constituents considered for grouping:** 12 elements	**Grouping method:** PCA # **of groups:** 2	**Groups/ Factors/ Sources:** Cr/Al/Si/Ti/Fe/Cu ("crustal"), Zn/As/V/Ni/Pb/ Se	**PM variables used:** NR
	Results: Cr/Al/Si/Ti/Fe/Cu associated with IL-8 release in normal human bronchial epithelial cells and IL-6 release in AM. Zn/As/V/Ni/Pb/Se not associated with any endpoints. Stepwise linear regression with individual constituents Fe and Si associated with IL-6 release in AM. Cr associated with IL-8 release in NHBE cells.					
Reference: Clarke et al. (2000, 013252) **Location:** Boston, MA **Particle Size:** $PM_{2.5}$	**Subjects:** Dogs **Exposure:** CAPs (avg for all studies, paired: 203.4, crossover: 360.8 µg/m3) repeated exposure with several weeks in between	**N:** 10 dogs, 20 paired exposures, 24 crossover	**Constituents considered for grouping:** 19 elements, black C	**Grouping method:** PCA # **of groups:** 4 for exposure in paired runs,6 for exposure in crossover runs	**Groups/ Factors/ Sources:** V/Ni, S, Al/Si, Br/Pb, S, Na/Cl, Cr	**PM variables used:** All elements, then factor scores
	Results: No significant differences between baseline, sham, or CAPs group for BAL cell differential percentages. Total BAL protein increased with CAPs compared to sham. No significant hematological effects with CAPs exposure. Mixed linear regression analyses (statistics not provided): Al and Ti (3-day avg. concentrations) associated with dose-dependent decreases in BAL AM and increases in BAL PMN percentages. Sulfate associated with increased WBC. BC, Al, Mn, Si, Zn, Ti, V, Fe, Ni associated with increased blood PMN. Na associated with increased blood lymphocytes. Al, Mn, Si associated with decreased blood lymphocytes. CAPs mass and BC associated with decreased blood eosinophils. CAPs mass associated with decreased platelet count. Regression using results of factor analysis: None for 3-day avg. concentration for BAL parameters. V/Ni for increased AM percentage and Br/Pb for increased PMN percentage for 3rd-day only concentration. V/Ni and Al/Si for increased blood PMN percentage and decreased blood lymphocyte percentage. Al/Si also for increased WBC counts. Na/Cl for increased blood lymphocyte percentage. S for decreased RBC and hemoglobin.					
Reference: Duvall et al. (2008, 097969) **Location:** 5 US cities **Particle Size:** $PM_{2.5}$	Subjects Primary human airway epithelial cells (100,000 cells/mL; dose not provided) **Exposure:** NR	**N:** NR	**Constituents considered for grouping:** NR	**Grouping method:** CMB, but not on coarse and ultrafine # **of groups:** 6 or 7	**Groups/ Factors/ Sources:** Mobile, residual, oil, wood, soil, secondary SO_4, secondary NO_3	**PM variables used:** Mass contribution of constituents, then mass contribution of sources
	Results: Linear regression with individual constituents: Sulfate associated with increased IL-8 mRNA expression. Sr associated with increased COX-2 and decreased HO-1 mRNA expressions. K associated with decreased HO-1 mRNA expression. Linear regression with sources: Significance levels not provided.					

Reference: Godleski et al. (2002, 156478) **Location:** Boston, MA **Particle Size:** NR	**Subjects:** Rats **Exposure:** CAPs (3-day mean CAPs concentration range: 126.1-481.0 µg/m3)	**N:** 7-10 rats × 2 levels CAPs × 2 levels SO_2 × 6 runs in different seasons	**Constituents considered for grouping:** 20 elements, OC, EC	**Grouping method:** Previous study in same city (Clarke et al.), and PCA of this experiment's data **# of groups:** 4	**Groups/ Factors/ Sources:** V/Ni, S, Al/Si/Ca, Br/Pb	**PM variables used:** 4 tracers (I, SO_4,V, Pb) and EC, OC
	Results: Increased percent of PMNs in BALF in CAPs-exposed rats at 24 h. CAPs affected lung tissue mRNA involved in pro-inflammation, immune, and vascular endothelial responses. Linear regression: Increased PMN associated with CAPs mass, Br, Pb, SO_4, EC, and OC.					
Reference: Gurgueira et al. (2002, 036535) **Location:** Boston, MA **Particle Size:** $PM_{2.5}$	Subjects Rats (Sprague Dawley) **Exposure:** CAPs (avg. mass concentration 600 µg/m3); also carbon black and ROFA	**N:** 13 experiments (1 rat/group at each time point)	**Constituents considered for grouping:** 20 elements	**Grouping method:** No grouping was performed **# of groups:** NA	**Groups/ Factors/ Sources:** NR	**PM variables used:** Mass contribution of every constituent
	Results: Increased oxidative stress in heart and lungs following CAPs exposure (and ROFA exposure). Univariate regression: Mn, Zn, Fe, Cu, and Ca most significant responses for lung (r^2>0.40). Al, Si, Ti, Fe, and total mass most significant response for heart (r^2>0.49).					
Reference: Kodavanti et al. (2005, 087946) **Location:** RTP, NC **Particle Size:** $PM_{2.5}$	Subjects Rats (SH and WKY) **Exposure:** CAPs (144-2758 µg/m3)	**N:** 6 1-day , 1-strain runs, 7 2-day, 2-strain runs, 4-9 rats per run.	**Constituents considered for grouping:** NR	**Grouping method:** No grouping was performed **# of groups:** NA	**Groups/ Factors/ Sources:** NR	**PM variables used:** Mass contribution of every constituent
	Results: No significant correlations between biologic responses and exposure variables (i.e., CAP mass, OC, inorganic C, sulfate, and other major elemental constituents). Al, Cu, Zn correlated with biologic responses when constituents normalized per unit mass of CAP (µg/mg). Zn correlated with plasma fibrinogen in SH rats (p = 0.0023).					
Reference: Lippmann et al. (2005, 087453) **Location:** Rural location upwind from New York City **Particle Size:** $PM_{2.5}$	**Subjects:** Mice (C57 and ApoE) **Exposure:** CAPs (avg. mass concentration 113 µg/m^3)	**N:** C57: 3-6 mice/group $ApoE^{-/-}$: 9-10 mice/group	**Constituents considered for grouping:** 19 elements + OC, EC, NO_3	**Grouping method:** (Absolute) PCA **# of groups:** 4	**Groups/ Factors/ Sources:** Regional SO_4 (S/Si/OC); Resuspended soil (CA/Fe/Al/Si);RO power plants (V/Ni/Se); traffic and unknown	**PM variables used:** Mass contribution of sources
	Results: ApoE null mice: Resuspended soil associated with decreased HR during exposure, but increased HR after exposure. Secondary sulfate associated with decreased HR after exposure. Residual oil associated with increased RMSSD and SDNN in afternoon following exposure. Secondary sulfate associated with decreased RMSSD and SDNN in night following exposure. Resuspended soil associated with increased RMSSD at night following exposure. PM mass associated with decreased HR during exposure and decreased RMSSD at night following exposure. **C57 mice:** Motor vehicle/other source category associated with decrease in RMSSD in afternoon following exposure					
Reference: Lippmann et al. (2006, 091165) **Location:** Rural location upwind from New York City **Particle Size:** $PM_{2.5}$	**Subjects:** Mice ($ApoE^{-/-}$) **Exposure:** CAPs (avg. mass concentration 85.6 µg/m^3)	**N:** 12 $ApoE^{-/-}$ mice (6/group)	**Number of Constituents considered for grouping:** NR	**Grouping method:** No grouping was performed **# of groups:** NR	**Groups/ Factors/ Sources:** NR	**PM variables used:** Mass contribution of every constituent in CAPs portion of study, contribution of 16 constituents in epi portion
	Results: Lag for HR elevations on 14 days with wind from NW was same day. Lag for SDNN reduction on 14 days with wind from NW was 0, 1 and 2. GAM analysis: B coefficient significant for Ni and HR (but not V, Cr, or Fe). B coefficient significant for Ni and log SDNN (but not V, Cr, or Fe).					

Reference: Maciejczyk and Chen (2005, 087456) **Location:** Rural; upwind from New York City **Particle Size:** $PM_{2.5}$	**Subjects:** NR **Exposure:** CAPs (90,000/well; 300 µg/mL)	**N:** 110 samples	**Constituents considered for grouping:** 19 elements + OC, EC, NO_3	**Grouping method:** (Absolute) PCA # **of groups:** 4	**Groups/ Factors/ Sources:** Regional SO_4 soil; unknown oil combustion	**PM variables used:** Mass contribution of sources
	Results: Correlation: V and Ni positively correlated with NF-κB. Oil combustion correlated the greatest with NF-κB (0.316). Significance not provided. Only 2% of mass contribution originates from this source.					
Reference: Nikolov et al. (2008, 156808) **Location:** Boston, MA **Particle Size:** NR	**Subjects:** Dogs **Exposure:**	**N:** 8 dogs, 24 exposure-days in 1997-98; 4 dogs, 21 exposure-days in 2001-2002	**Constituents considered for grouping:** 13 elements, BC, EC, OC	**Grouping method:** Compared 3 factor-analytic models within a SEM model # **of groups:** 4	**Groups/ Factors/ Sources:** Oil Combustion V/Ni; power plants S ;road dust Al/Si ;motor vehicles BC/OC/EC	**PM variables used:** Mass contribution of every constituent
	Results: Univariate response for respiratory outcomes: road dust and oil combustion associated with decreased respiratory frequency; motor vehicles associated with increased respiratory frequency; motor vehicles associated with increased PEF; road dust associated with decreased penh and motor vehicles associated with increased penh. **Multivariate responses for respiratory outcome:** Road dust associated with decreased respiratory rate; Motor vehicles associated with increased airway irritation.					
Reference: Rhoden et al. (2004, 087969) **Location:** Boston, MA **Particle Size:** $PM_{2.5}$	**Subjects:** Rats (Sprague-Dawley) **Exposure:** CAPs (avg. mass concentration range 150-2520 µg/m3) acetylcysteine full factorial	**N:** 4-8 rats (1-2 per group - sham, CAPs, sham/NAC, CAP/NAC) 10 exposures	**Constituents considered for grouping:** 20 elements	**Grouping method:** No grouping was performed # **of groups:** NA	**Groups/ Factors/ Sources:** NR	**PM variables used:** Mass contribution of every constituent
	Results: Increased oxidative stress and inflammation in lungs of CAPs animals that was attenuated with NAC. **Univariate regression:** Al, Si, Fe, K, Pb, and Cu most significantly correlated with lung TBARS. No significant correlations for lung carbonyls or lung PMN.					
Reference: Saldiva et al. (2002, 025988) **Location:** Boston, MA **Particle Size:** $PM_{2.5}$	**Subjects:** Rats (Sprague-Dawley **Exposure:** CAPs (3-day avg. mass concentration range 126.1-481 µg/m3)	**N:** 7-10 rats/group (air/sham, SO_2/sham, air/CAP, SO_2/CAP) × 6 runs in different seasons	**Constituents considered for grouping:** 15 elements (used Clarke 2000 to select tracers)	**Grouping method:** Previous study in same city (Clarke et al. 2000) # **of groups:** 6	**Groups/ Factors/ Sources:** V/Ni S Al/Si Br/Pb Na/Cl Cr	**PM variables used:** Mass contribution of 8 elements in univariate step. Tracers (Si, SO_4, V, Pb, Br, Cl) and EC, OC in multivariate step.
	Results: Increased percent and number of PMN in majority of air and SO_2 rats exposed to CAPs, but significance levels not provided. Other responses (protein, LDH, NAG) were variable and depended upon the CAPs exposure. No CAPs effect on histopathology. **Linear regression:** V, Br, Pb, SO_4, EC, OC, Si, CAP mass associated with increased PMN and lymphocytes for normal+CB rats. Only V not associated with PMN in normal rats. Lymphocyte response due to CB rats, but not observed for SO_4 , Si, or mass in this group. Br, Pb, SO_4, EC, OC, Si associated with increased total protein in CB rats. Cl and V associated with decreased LDH in CB rats. No BAL effects in normal rats exposed to CAPs. V, Br, Pb, EC, OC, and Cl associated with increased neutrophil density in lungs of normal rats.					
Reference: Seagrave et al. (2006, 091291) **Location:** 4 SE US sites for 2 seasons **Particle Size:** $PM_{2.5}$	Subjects Rats (Fisher 344) **Exposure:** 0.75, 1.5 and 3 mg/rat via intratracheal instillation	**N:** 5 rats/dose	**Constituents considered for grouping:** NR	**Grouping method:** CMB # **of groups:** 13	**Groups/ Factors/ Sources:** secondary NO_3; secondary NH_4; secondary SO_4; coke production; vegetative detritus; natural gas combust; road dust; wood combust; meat cooking gasoline; diesel other OM; other mass	**PM variables used:** Mass contribution of every constituent, then mass contribution of sources
	Results: Potency depended upon season and site of sample collection. In general, effects were greater in the winter. **PLS analysis**: 2 major constituents identified (OC, Pb, hopanes/steranes, nitrate, As for first and major metal oxides for the second), gasoline most important predictor for both constituents, with diesel influencing second constituent and nitrate influencing first constituent. First constituent affected cytotoxic responses, second constituent affected inflammatory responses.					

Reference: Veranth et al. (2006, 087479) **Location:** 8 sites in the western US **Particle Size:** $PM_{2.5}$	**Subjects:** BEAS-2B cells (35000 cells/cm2; 10, 20, 40, 80 µg/cm2) **Exposure:** Loose surface soil sweepings through mechanical tumbler and cascade impactor	**N:** 6; 16 runs over 6 mo	**Constituents considered for grouping:** 13 elements, TC, 5 OC variables, 4 EC variables, 2 ions, EU, one ratio (Ca: Al), OP, CO_3	**Grouping method:** PLS **# of groups:** NR	**Groups/ Factors/ Sources:** NR	**PM variables used:** Mass contribution every constituent (?)
	Results: Dose-related increase in IL-6 and decreases in cell viability for all soil types. IL-8 responses more variable and dependent upon soil type. Univariate correlations. Low correlations for all constituents tested with IL-6. Highest correlations for EC1 (R^2 = 0.50) and pyrolyzed OC (R^2 = 0.46), then Ca/Al (R^2 = 0.21). Carbonate carbon, EC3, and Sr correlated with IL-8 (R^2 = 0.27, 0.13, and 0.25, respectively). EC and Ni correlated with IL-8 trend over the range of 10-80 µg/cm2 (R^2 = 0.39 and 0.27, respectively). Multivariate redundancy analysis OC1, OC3, OC2, EC2, Br, EC1, Ni correlated with IL-8 release, decreased viability, and decreased IL-6 at low and high doses. Ni, EC1, and EC2 correlated with IL-6 release at the high dose, decreased IL-6 at the low dose, decreased IL-8 release, and decreased viability. Br was negatively associated.					
Reference: Wellenius et al. (2003, 055691) **Location:** Boston, MA **Particle Size:** $PM_{2.5}$	**Subjects:** Dogs **Exposure:** CAPs (avg. mass concentration range 161.3-957.3 µg/m^3) repeated exposure with several weeks in between	**N:** 6 dogs, 20 exposures	**Constituents considered for grouping:** 15 elements (+EC OC?) (used Clarke et al. 2000)	**Grouping method:** Previous study in same city (Clarke et al. 2000) **# of groups:** 6 (but did not use all in analysis of health effects)	**Groups/ Factors/ Sources:** V/Ni S Al/Si Br/Pb Na/Cl Cr	**PM variables used:** Univariate: Mass Number Ni, S, Si, BC Multivariate: Ni, S, Si , BC
	Results: ST-segment elevation increased with CAPs. **Univariate regression:** Si and Pb associated with peak ST-segment elevation and integrated ST-segment change.CAPs mass or number concentration were not associated with any change. **Multivariate regression:** Si associated with peak ST-segment elevation and integrated ST-segment change.					
Reference: Zhang et al. (2008, 192008) **Location:** Metro area of Denver, CO/ 45 samples through 1 yr **Particle Size:** 2.5; filtered to 0.22 um	**Subjects:** Alveolar macrophage cell line (NR8383); 1 ×106 cells/ml **Exposure:** Soluble components exposure concentration range from 20-200 pg of PM/cell	**N:** 45 PM samples, 3 runs	**Constituents considered for grouping:** 43 + EC, OC	**Grouping method:** PMF **# of groups:** 9	**Groups/Factors/ Sources:** Mobile, water soluble carbon, sulfate, soil, iron, Cd and Zn point source, Pb, pyrotechnics, platinum	**PM variables used:** Mass contribution of sources
	Results: Started with regression on 9 sources, then 3 (water-soluble carbon factor, soil dust source, iron source). Soil dust source was not significant. Final regression model excluded 3 days of outliers (Fe source most significant, then water-soluble carbon factor, then soil dust source) for ROS effects, with adjusted R^2 of 0.774. Fe source likely associated with industrial source and includes high loadings of water-soluble Fe and Ti (not identified); water-soluble C factor derived from both secondary organic aerosol and biomass smoke (largely consists of polar organic compounds); soil dust source identified by water-soluble resuspended dust elements and contains Mg and Ca.
